

# Machine Translation

Dan Klein  
UC Berkeley

Many slides from John DeNero and  
Philip Koehn

## Translation Task

---

- Text is both the input and the output.
- Input and output have roughly the same information content.
- Output is more predictable than a language modeling task.
- Lots of naturally occurring examples.

## Translation Examples

## English-German News Test 2013 (a standard dev set)

---

Republican leaders justified their policy by the need to combat electoral fraud.

Die	Führungskräfte	der	Republikaner
The	Executives	of the	republican
rechtfertigen	ihre	Politik	mit der
justify	your	politics	With of the
Notwendigkeit	,	den	Wahlbetrug zu
need	,	the	election fraud to
bekämpfen	.		
fight	.		

## Variety in Translations?

Human-generated reference translation

A small planet, whose is as big as could destroy a middle sized city, passed by the earth with a distance of 463 thousand kilometers. This was not found in advance. The astronomists got to know this incident 4 days later. This small planet is 50m in diameter. The astronomists are hard to find it for it comes from the direction of sun.

A commercial system from 2002

A volume enough to destroy a medium city small planet is big, flite earth within 463,000 kilometres of close however were not in advance discovered, astronomer just knew this matter after four days. This small planet diameter is about 50 metre, from the direction at sun, therefore astronomer very hard to discovers it.

Google Translate 2020

From <https://catalog.ldc.upenn.edu/LDC2003T17>

An asteroid that was large enough to destroy a medium-

## Evaluation

## BLEU Score

BLEU score: geometric mean of 1-, 2-, 3-, and 4-gram precision vs. a reference, multiplied by brevity penalty (harshly penalizes translations shorter than the reference).

$$\text{Matched}_i = \sum_{t_i} \min \left\{ C_h(t_i), \max_j C_j(t_i) \right\}$$

If "of the" appears twice in hypothesis h but only at most once in a reference, then only the first is "correct"

$$P_i = \frac{\text{Matched}_i}{H_i}$$

"Clipped" precision of n-gram tokens

$$B = \exp \left\{ \min \left( 0, \frac{n - L}{n} \right) \right\}$$

Brevity penalty only matters if the hypothesis **corpus** is shorter than the sum of (shortest) references.

$$\text{BLUE} = B \left( \prod_{i=1}^4 P_i \right)^{\frac{1}{4}}$$

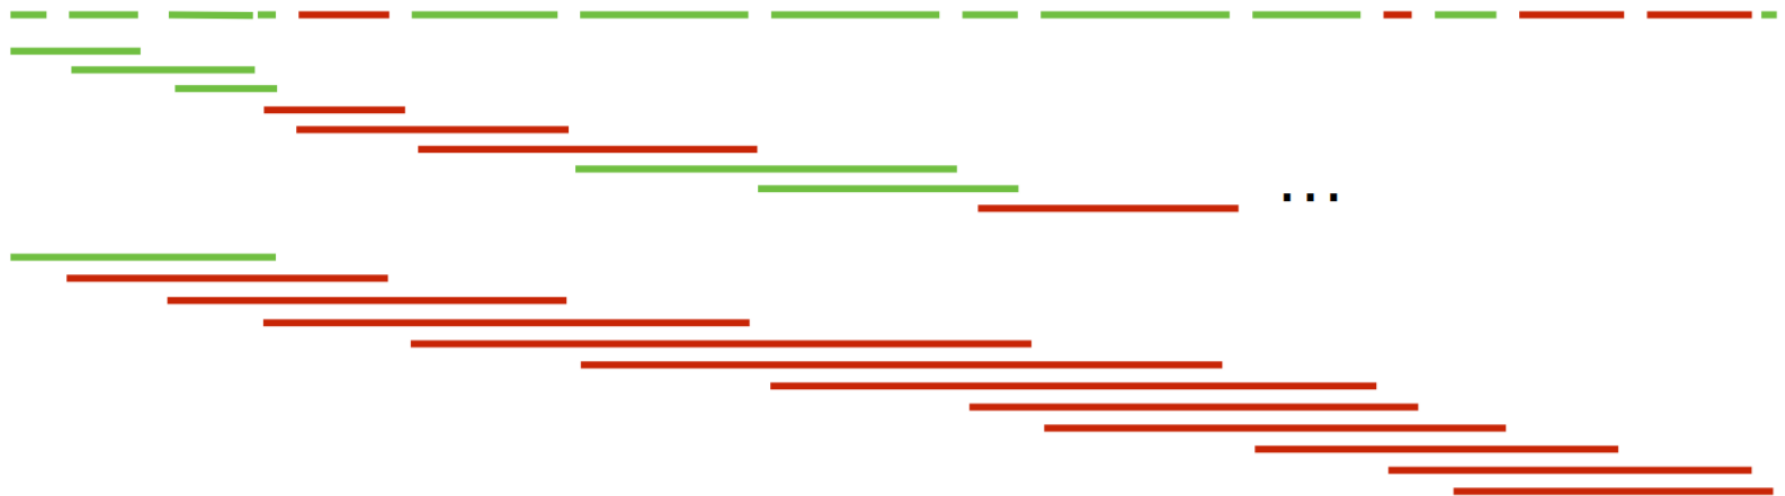

BLEU is a mean of clipped precisions, scaled down by the brevity penalty.

## Evaluation with BLEU

---

In this sense, the measures will partially undermine the American democratic system.

In this sense, these measures partially undermine the democratic system of the United States.

BLEU = 26.52, 75.0/40.0/21.4/7.7 (BP=1.000, ratio=1.143, hyp\_len=16, ref\_len=14)

(Papineni et al., 2002) BLEU: a method for automatic evaluation of machine translation.

## Corpus BLEU Correlations with Average Human Judgments

These are ecological correlations over multiple segments; segment-level BLEU scores are noisy.

Commercial machine translation providers seem to all perform human evaluations of some sort.

(Ma et al., 2019)  
Results of the WMT19 Metrics Shared Task:  
Segment-Level and Strong MT Systems Pose Big Challenges

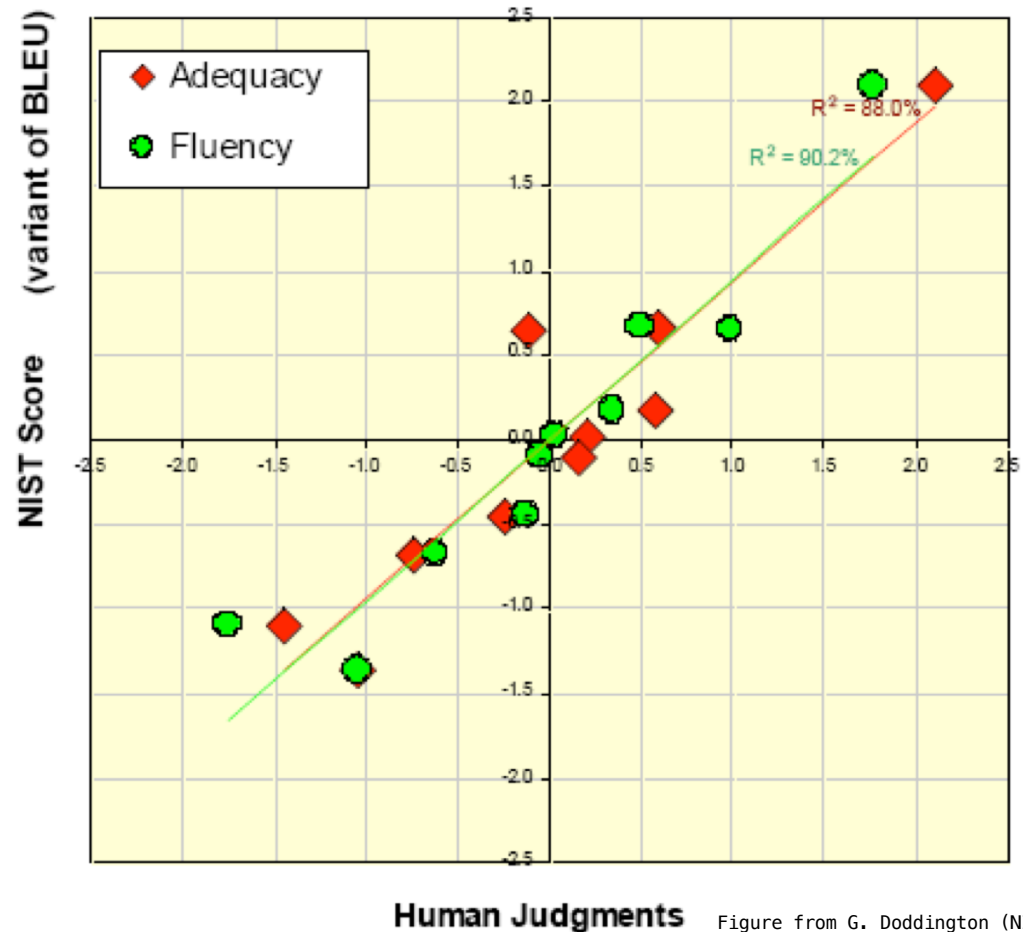

Figure from G. Doddington (NIST)

# Human Evaluations

## Direct assessment: adequacy & fluency

- **Monolingual:** Ask humans to compare machine translation to a human-generated reference. (Easier to source annotators)
- **Bilingual:** Ask humans to compare machine translation to the source sentence that was translated. (Compares to human quality)
- Annotators can assess segments (sentences) or whole documents.
- Segments can be assessed with or without document context.

## Ranking assessment:

- Raters are presented with 2 or more translations.
- A human-generated reference may be provided, along with the source.
- "In a pairwise ranking experiment, human raters assessing adequacy and fluency show a

1/12 documents, 4 items left in document WMT20DocSrcDA #214: Doc. #seattle\_times.7674-2 English → German (deutsch)

Below you see a document with 6 sentences in English and their corresponding candidate translations in German (deutsch). Score each candidate translation in the document context, answering the question:

How accurately does the candidate text (right column, in bold) convey the original semantics of the source text (left column) in the document context?

You may revisit already scored sentences and update their scores at any time by clicking at a source text.

(Akbari et al., 2021) Findings of the 2021 Conference on Machine Translation

## Translationese and Evaluation

---

Translated text can: (Baker et al., 1993; Graham et al., 2019)

- be more explicit than the original source
- be less ambiguous
- be simplified (lexically, syntactically, and stylistically)
- display a preference for conventional grammaticality
- avoid repetition
- exaggerate target language features
- display features of the source language

"If we consider only original source text (i.e. not translated from another language, or translationese), then we find evidence showing that human parity has not been achieved."

(Toral et al., 2018)

(Baker et al., 1993) Corpus linguistics and translation studies: Implications and applications.  
(Graham et al., 2019) Translationese in Machine Translation Evaluation.  
(Toral et al, 2018) Attaining the Unattainable? Reassessing Claims of Human Parity in Neural Machine Translation

## How are We Doing? Example: WMT 2019 Evaluation

---

2019 segment-in-context direct assessment (Barrault et al, 2019):

- |   |  |
|---|--|
| ✓ German to English: many systems are tied with human performance;  | × English to Gujarati: all systems are outperformed by the human translator;   |
| × English to Chinese: all systems are outperformed by the human translator;   | × English to Kazakh: all systems are outperformed by the human translator;     |
| × English to Czech: all systems are outperformed by the human translator;   | × English to Lithuanian: all systems are outperformed by the human translator; |
| × English to Finnish: all systems are outperformed by the human translator;   | ✓ English to Russian: Facebook-FAIR is tied with human performance.            |
| ✓ English to German: Facebook-FAIR achieves super-human translation performance; several systems are tied with human performance; |  |

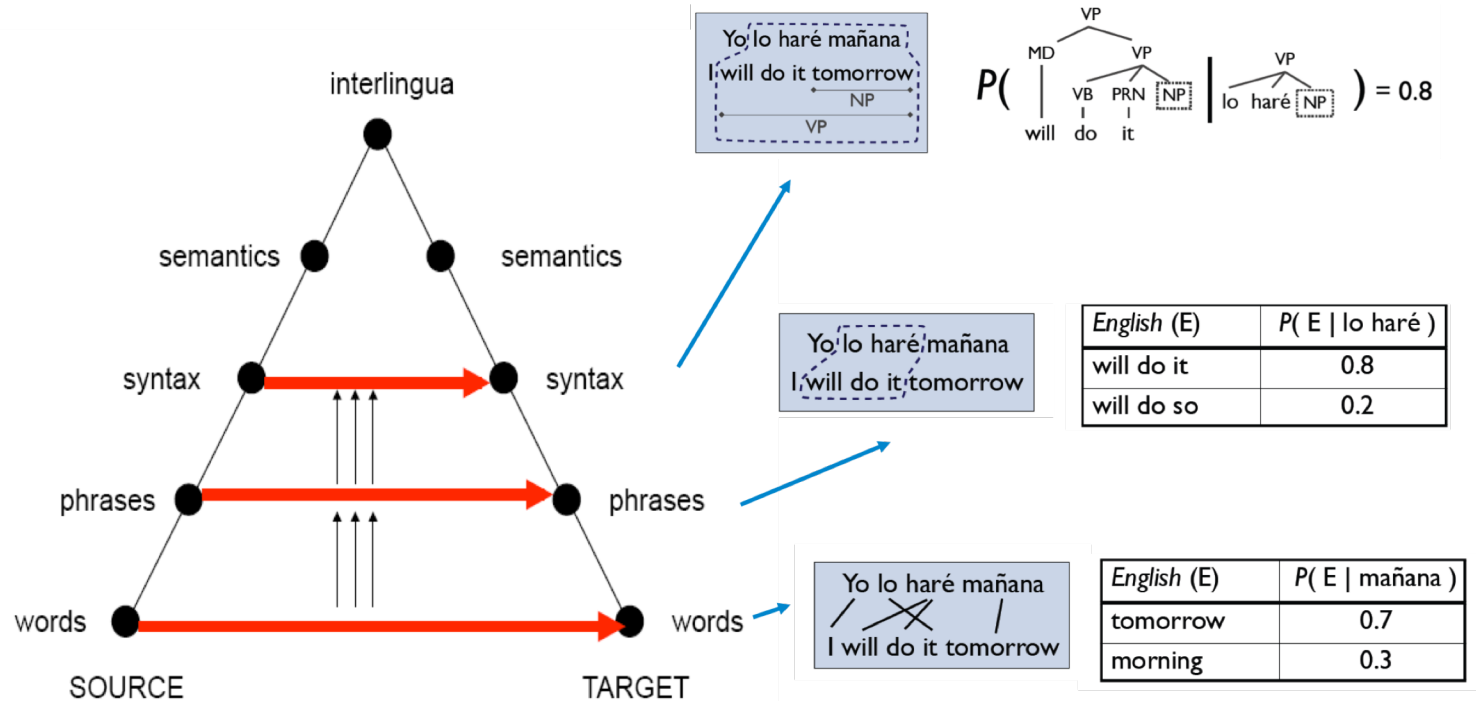

# Statistical Machine Translation (1990 - 2015)

When I look at an article in Russian, I say: "This is really written in English, but it has been coded in some strange symbols. I will now proceed to decode."

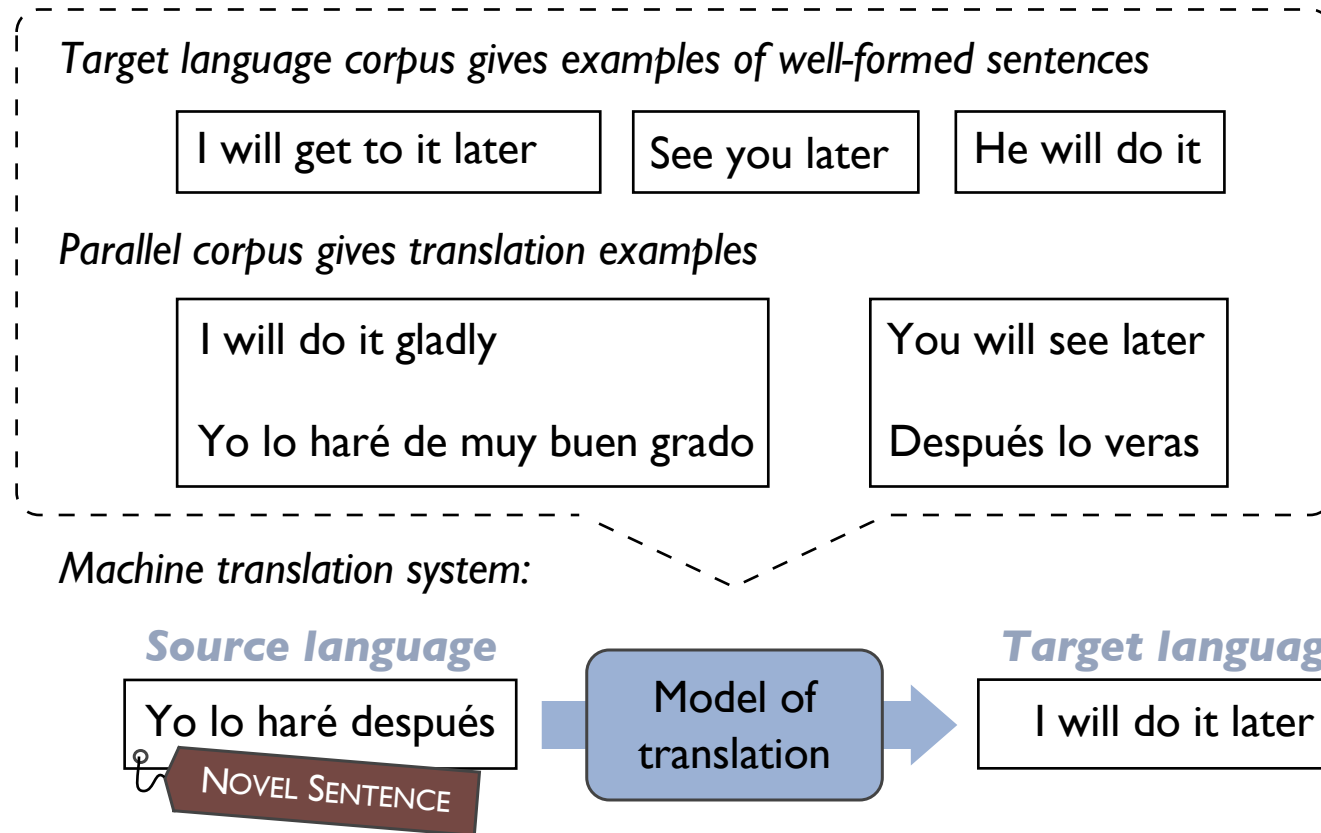

Warren Weaver (1949)

## Levels of Transfer: Vauquois Triangle (1968)

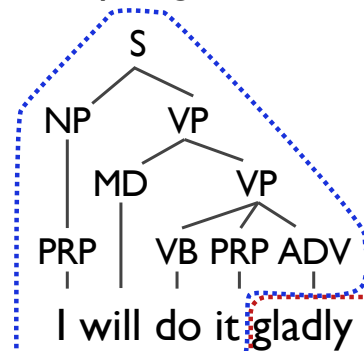

## Data-Driven Machine Translation

---

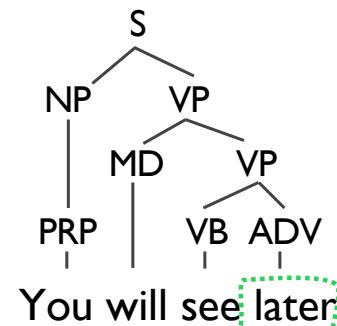

## Stitching Together Fragments

*Parallel corpus gives translation examples*

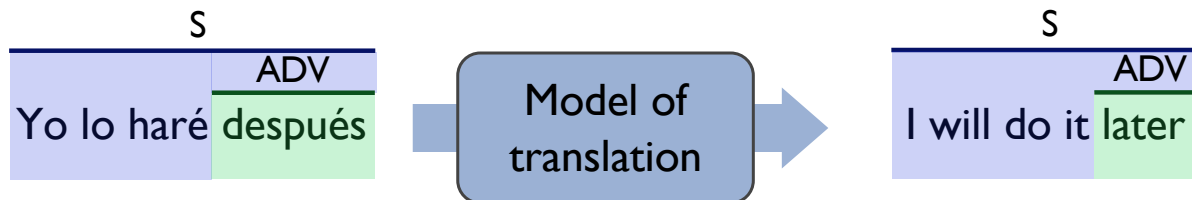

Yo lo haré de muy buen grado

Después lo veras

*Machine translation system:*

## Evolution of the Noisy Channel Model

---

$$P(e|f) \propto P(f|e) \cdot P(e)$$

$$P(e|f) \propto P(f|e)^{\phi_{\text{tm}}} \cdot P(e)^{\phi_{\text{lm}}}$$

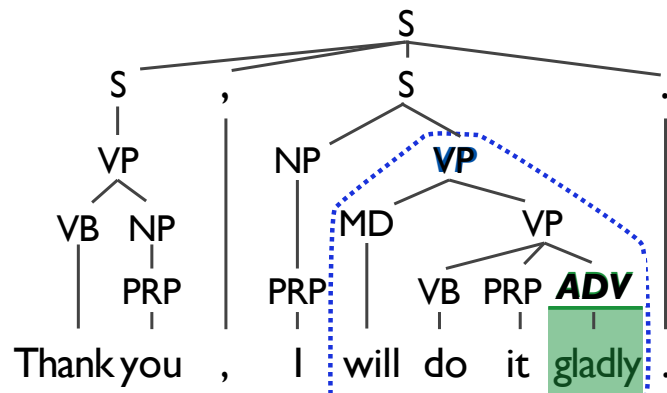

$$P(e|f) \propto \exp \left\{ \sum_i w_i \cdot f_i(e, f) \right\}$$

Chosen to minimize loss

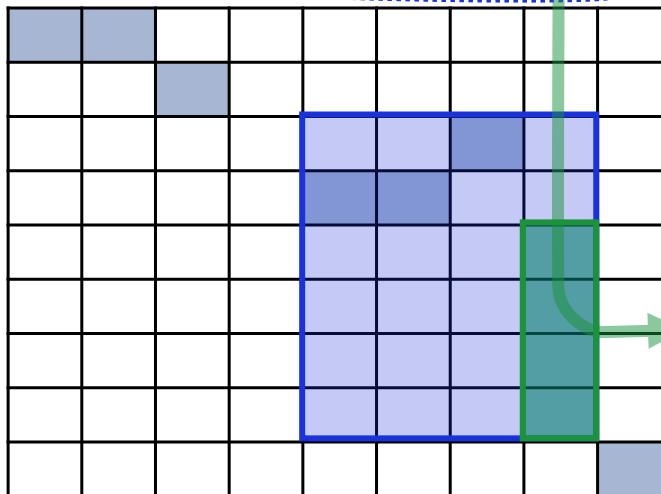

E.g.,  $\log P(e)$

## Word Alignment and Phrase Extraction

## Extracting Translation Rules

Frequency statistics on these rules serve as features in a translation model

Gracias

,  
lo  
haré  
de  
muy  
buen  
grado

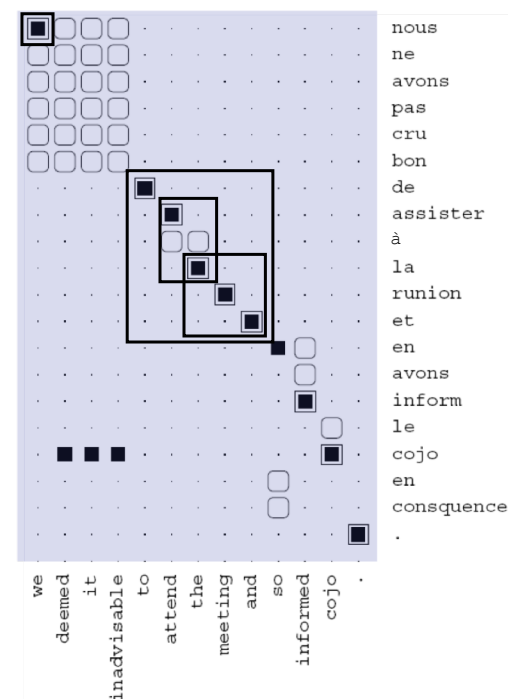

## Counting Aligned Phrases

---

d'assister à la reunion et ||| to attend the meeting and  
assister à la reunion ||| attend the meeting  
la reunion et ||| the meeting and  
nous ||| we  
...

- Relative frequencies are the most important features in a phrase-based or syntax-based model.
- Scoring a phrase under a lexical model is the second most important feature.
- Estimation does not involve choosing among segmentations of a sentence into phrases.

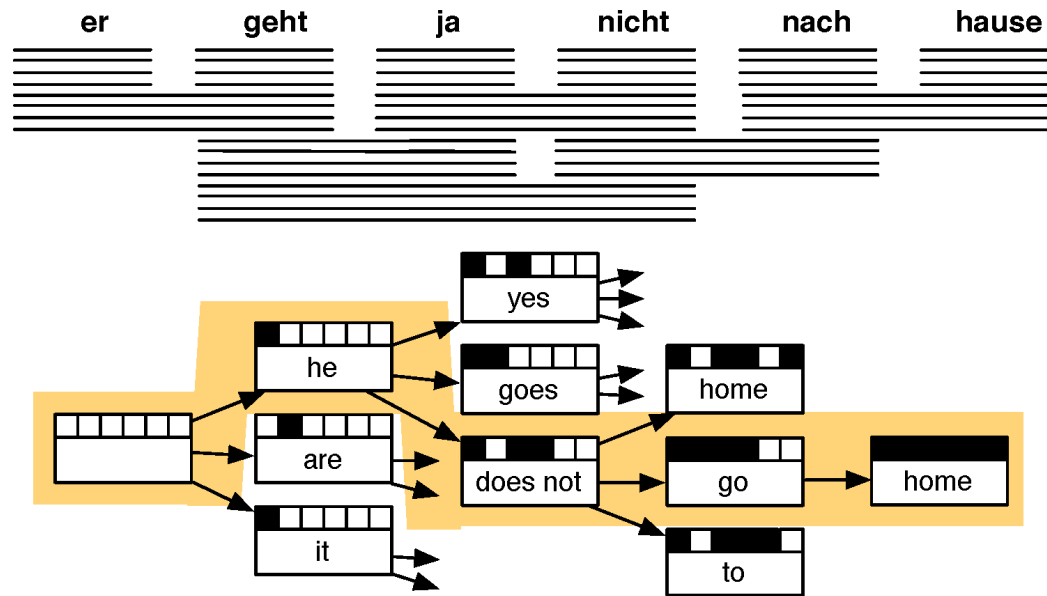

## Translation Options

er	geht	ja	nicht	nach	hause
he	is	yes	not	after	house
it	are	is	do not	to	home
, it	goes	, of course	does not	according to	chamber
, he	go	,	is not	in	at home
it is		not		home	
he will be		is not		under house	
it goes		does not		return home	
he goes		do not		do not	
	is		to		
	are		following

## Word Alignments

## Word Alignment?

	john	wohnt	hier	nicht
john				
does		?		?
not				
live				
here				

Is the English word **does** aligned to  
the German **wohnt** (verb) or **nicht** (negation) or neither?

## Word Alignment?

	john	biss	ins	grass
john				
kicked				
the				
bucket				

How do the idioms **kicked the bucket** and **biss ins grass** match up?  
Outside this exceptional context, **bucket** is never a good translation for **grass**

## Lexical Translation / Word Alignment Models

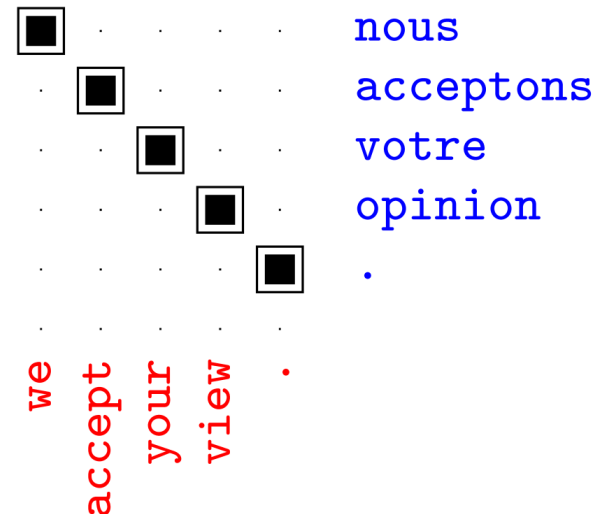

# Unsupervised Word Alignment

- Input: a **bitext**: pairs of translated sentences

nous acceptons votre opinion .  
we accept your view .

- Output: **alignments**: pairs of translated words
  - When words have unique sources, can represent as a (forward) alignment function  $a$  from French to English positions

## Word Alignment

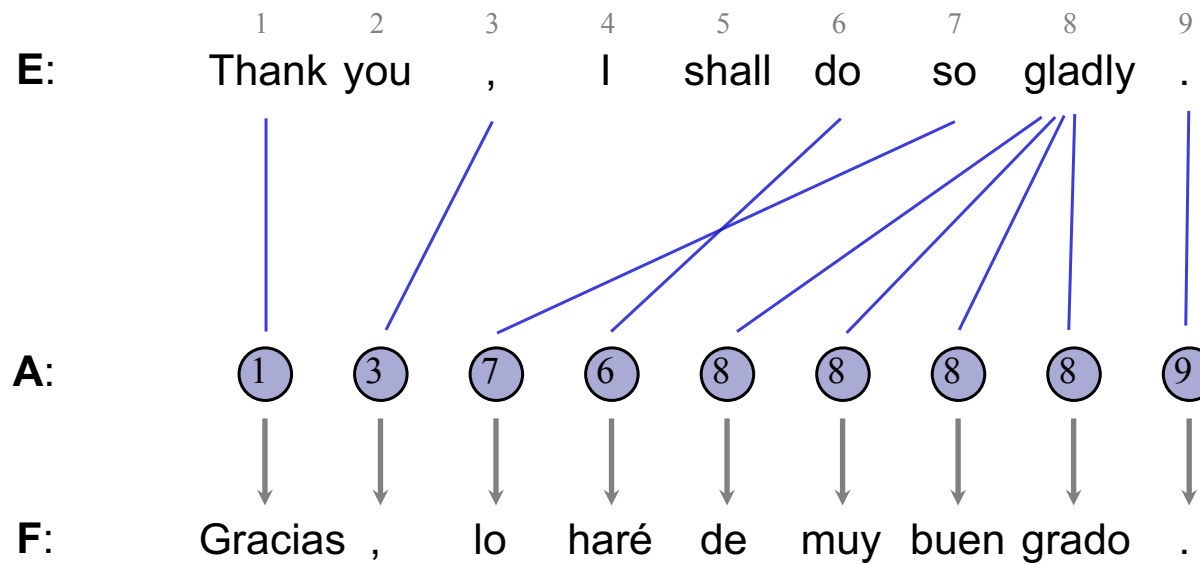

---

- Even today models are often built on the IBM alignment models
- Create probabilistic word-level translation models
- The models incorporate latent (unobserved) word alignments
- Optimize the probability of the observed words
- Use the imputed alignments to reveal word-level correspondence

## IBM Model 1: Allocation

# IBM Models 1/2

## Model Parameters

*Translation:*  $P(F_1 = \text{Gracias} \mid E_{A_1} = \text{Thank})$     *Alignment:*  $P(A_2 = 3)$

## Example

das		Haus		ist		klein	
$e$	$t(e f)$	$e$	$t(e f)$	$e$	$t(e f)$	$e$	$t(e f)$
the	0.7	house	0.8	is	0.8	small	0.4
that	0.15	building	0.16	's	0.16	little	0.4
which	0.075	home	0.02	exists	0.02	short	0.1
who	0.05	household	0.015	has	0.015	minor	0.06
this	0.025	shell	0.005	are	0.005	petty	0.04

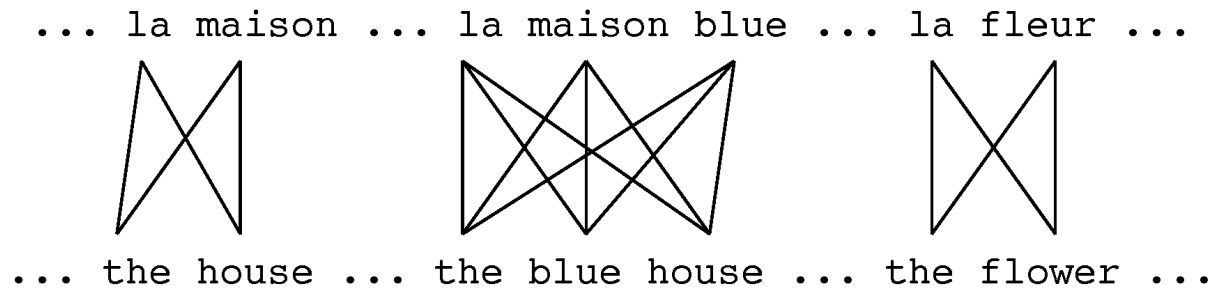

$$\begin{aligned}
 p(e, a|f) &= \frac{\epsilon}{4^3} \times t(\text{the}|\text{das}) \times t(\text{house}|\text{Haus}) \times t(\text{is}|\text{ist}) \times t(\text{small}|\text{klein}) \\
 &= \frac{\epsilon}{4^3} \times 0.7 \times 0.8 \times 0.8 \times 0.4 \\
 &= 0.0028\epsilon
 \end{aligned}$$

# Expectation Maximization

# EM Algorithm

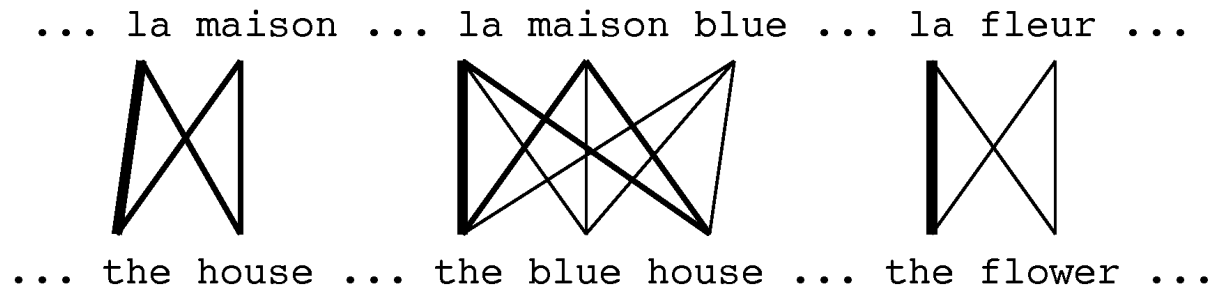

- Incomplete data
  - if we had *complete data*, would could estimate *model*
  - if we had *model*, we could fill in the *gaps in the data*
- Expectation Maximization (EM) in a nutshell
  1. initialize model parameters (e.g. uniform)
  2. assign probabilities to the missing data
  3. estimate model parameters from completed data
  4. iterate steps 2–3 until convergence

## EM Algorithm

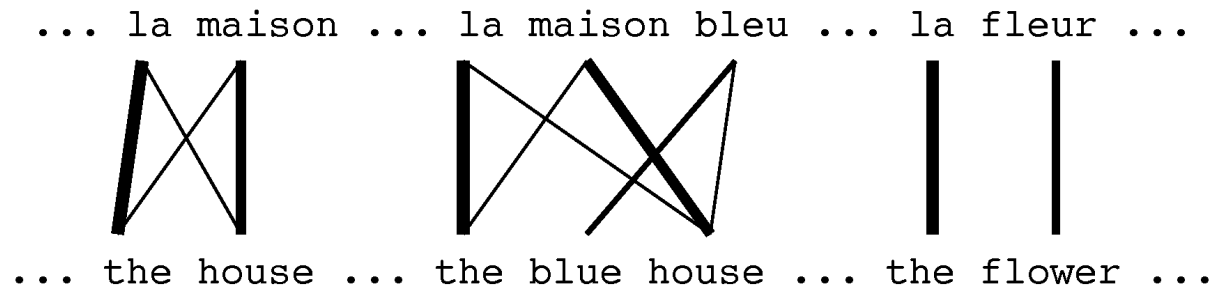

- Initial step: all alignments equally likely
- Model learns that, e.g., **la** is often aligned with **the**

## EM Algorithm

- After one iteration
- Alignments, e.g., between **la** and **the** are more likely

## EM Algorithm

- After another iteration
- It becomes apparent that alignments, e.g., between **fleur** and **flower** are more likely (pigeon hole principle)

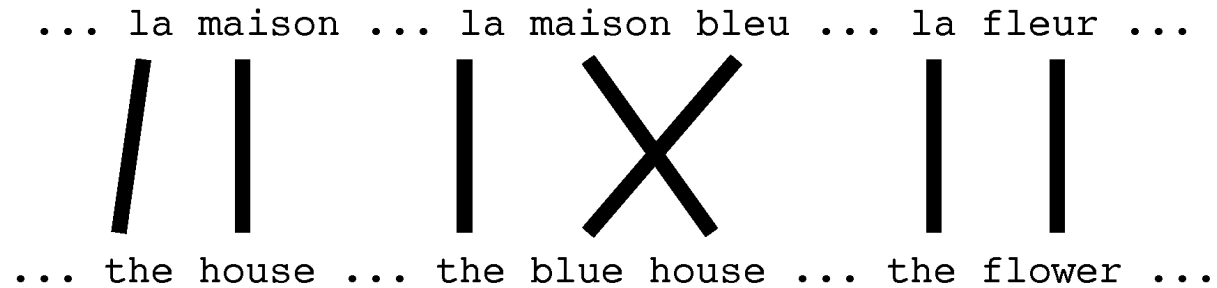

## EM Algorithm

... la maison ... la maison bleu ... la fleur ...  
/ | | X | |  
... the house ... the blue house ... the flower ...

- Convergence
- Inherent hidden structure revealed by EM

## EM Algorithm

... la maison ... la maison bleu ... la fleur ...  
... the house ... the blue house ... the flower ...

$p(\text{la}|\text{the}) = 0.453$   
 $p(\text{le}|\text{the}) = 0.334$   
 $p(\text{maison}|\text{house}) = 0.876$   
 $p(\text{bleu}|\text{blue}) = 0.563$   
...

- Parameter estimation from the aligned corpus

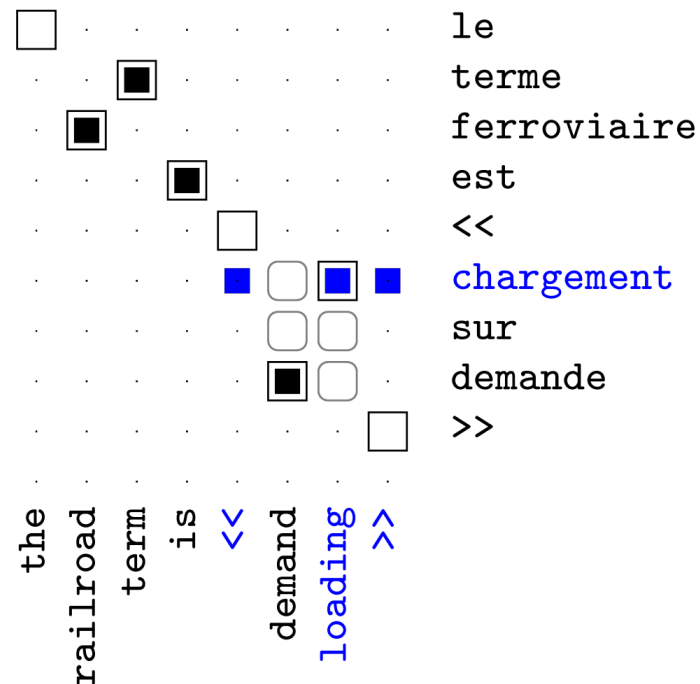

## IBM Model 1 and EM

- EM Algorithm consists of two steps
- Expectation-Step: Apply model to the data
  - parts of the model are hidden (here: alignments)
  - using the model, assign probabilities to possible values
- Maximization-Step: Estimate model from data
  - take assign values as fact
  - collect counts (weighted by probabilities)
  - estimate model from counts
- Iterate these steps until convergence

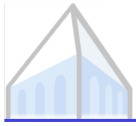

# Problems with Model 1

- There's a reason they designed models 2-5!
- Problems: alignments jump around, align everything to rare words
- Experimental setup:
  - Training data: 1.1M sentences of French-English text, Canadian Hansards
  - Evaluation metric: alignment error Rate (AER)
  - Evaluation data: 447 hand-aligned sentences

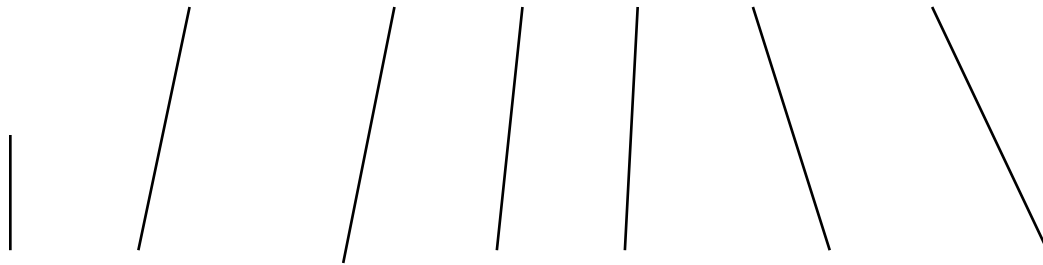

## IBM Model 2: Global Monotonicity

# Monotonic Translation

---

Japan shaken by two new quakes

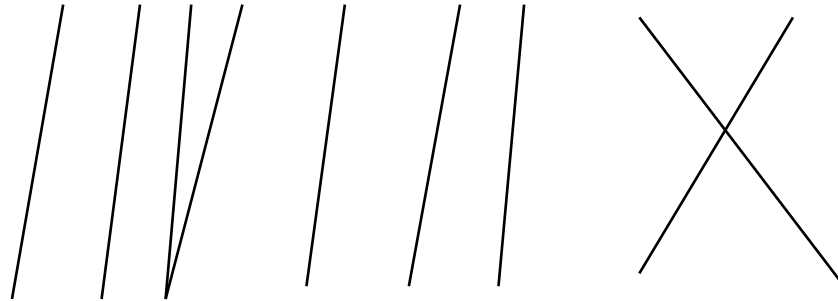

Le Japon secoué par deux nouveaux séismes

# Local Order Change

---

Japan is at the junction of four tectonic plates

Le Japon est au confluent de quatre plaques tectoniques

# IBM Model 2

---

- Alignments tend to the diagonal (broadly at least)

$$P(f, a|e) = \prod_j P(a_j = i|j, I, J) P(f_j|e_i) \\ P(dist = i - j\frac{I}{J}) \\ \frac{1}{Z} e^{-\alpha(i - j\frac{I}{J})}$$

# EM for Models 1/2

---

- Model 1 Parameters:

- Translation probabilities (1+2)

$$P(f_j|e_i)$$

- Distortion parameters (2 only)

$$P(a_j = i|j, I, J)$$

- Start with  $P(f_j|e_i)$  uniform, including  $P(f_j|null)$

- For each sentence:

- For each French position j

- Calculate posterior over English positions

$$P(a_j = i|f, e) = \frac{P(a_j = i|j, I, J)P(f_j|e_i)}{\sum_{i'} P(a_j = i'|j, I, J)P(f_j|e'_i)}$$

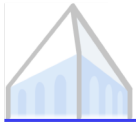

- (or just use best single alignment)

- Increment count of word  $f_j$  with word  $e_i$  by these amounts

- Also re-estimate distortion probabilities for model 2

- Iterate until convergence

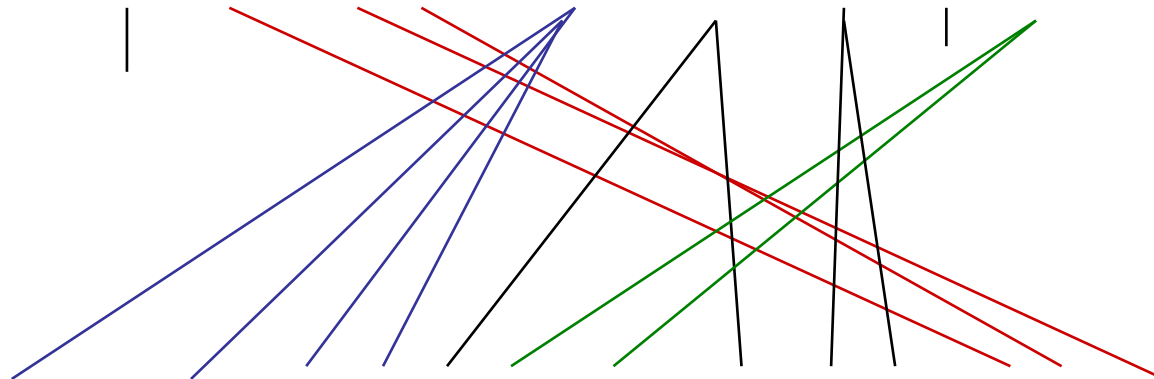

## HMM Model: Local Monotonicity

# Phrase Movement

---

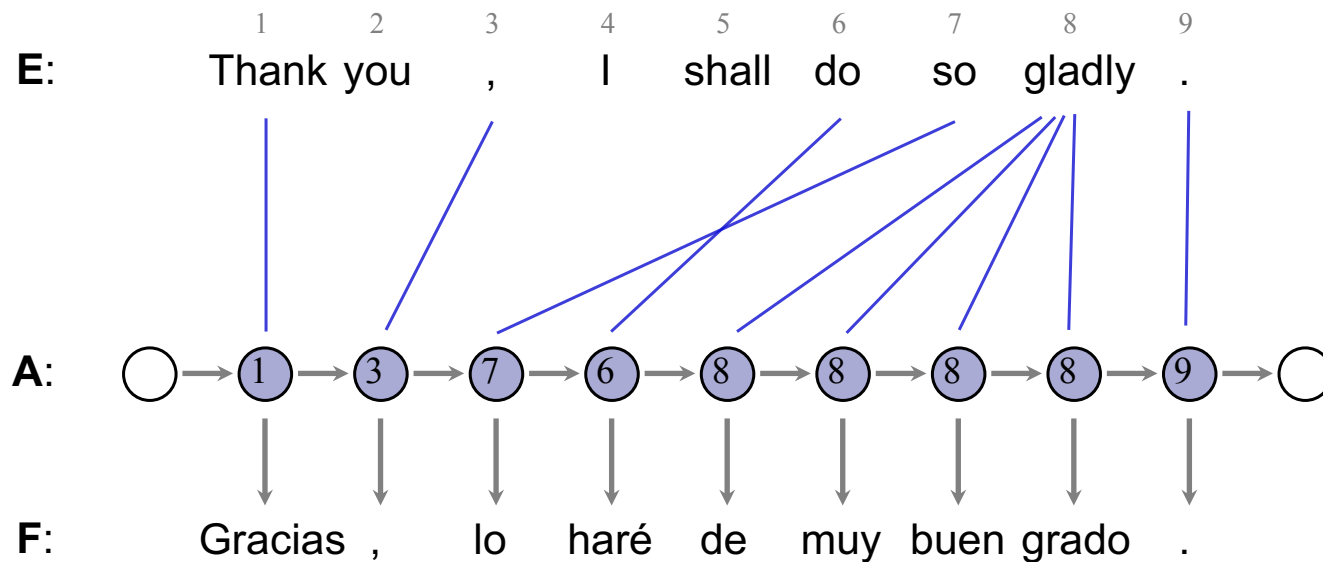

On Tuesday Nov. 4, earthquakes rocked Japan once again

Des tremblements de terre ont à nouveau touché le Japon jeudi 4 novembre.

# The HMM Model

## Model Parameters

*Emissions:*  $P(F_1 = \text{Gracias} \mid E_{A_1} = \text{Thank})$     *Transitions:*  $P(A_2 = 3 \mid A_1 = 1)$

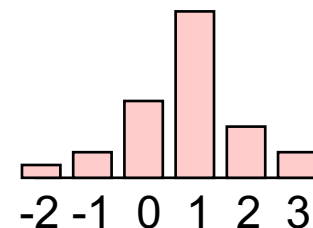

# The HMM Model

- Model 2 preferred global monotonicity
- We want local monotonicity:
  - Most jumps are small
- HMM model (Vogel 96)

f	$t(f   e)$
nationale	0.469
national	0.418
nationaux	0.054
nationales	0.029

$$P(f, a|e) = \prod_j P(a_j|a_{j-1})P(f_j|e_i)$$

$$P(a_j - a_{j-1})$$

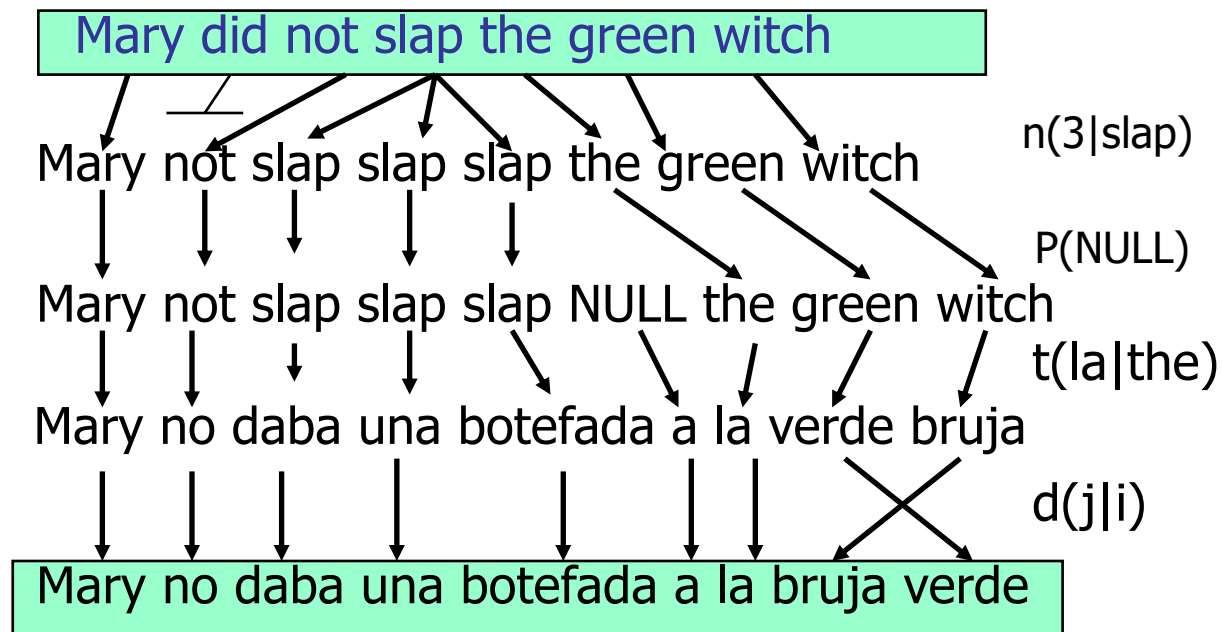

- Re-estimate using the forward-backward algorithm
  - Handling nulls requires some care
- What are we still missing?

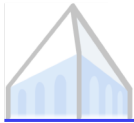

Models 3+: Fertility

## IBM Models 3/4/5

[from Al-Onaizan and Knight, 1998]

## Examples: Translation and Fertility

*the*

f	$t(f   e)$	$\phi$	$n(\phi   e)$
le	0.497	1	0.746
la	0.207	0	0.254
les	0.155		
l'	0.086		
ce	0.018		
cette	0.011		

*not*

f	$t(f   e)$	$\phi$	$n(\phi   e)$
ne	0.497	2	0.735
pas	0.442	0	0.154
non	0.029	1	0.107
rien	0.011		

*farmers*

f	$t(f   e)$	$\phi$	$n(\phi   e)$
agriculteurs	0.442	2	0.731
les	0.418	1	0.228
cultivateurs	0.046	0	0.039
producteurs	0.021		

## Example: Idioms

he is nodding  
/  
il hoche la tête

*nodding*

$f$	$t(f   e)$	$\phi$	$n(\phi   e)$
signe	0.164	4	0.342
la	0.123	3	0.293
tête	0.097	2	0.167
oui	0.086	1	0.163
fait	0.073	0	0.023
que	0.073		
hoche	0.054		
hocher	0.048		
faire	0.030		
me	0.024		
approuve	0.019		
qui	0.019		
un	0.012		
faites	0.011		

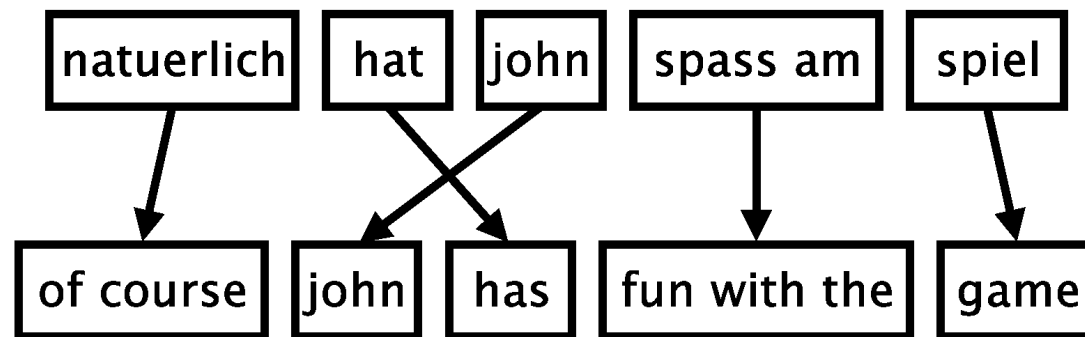

## Example: Morphology

---

*should*

f	$t(f   e)$	$\phi$	$n(\phi   e)$
devrait	0.330	1	0.649
devraient	0.123	0	0.336
devrions	0.109	2	0.014
faudrait	0.073		
faut	0.058		
doit	0.058		
aurait	0.041		
doivent	0.024		
devons	0.017		
devrais	0.013		

## Phrase-Based Model

- Foreign input is segmented in phrases
- Each phrase is translated into English
- Phrases are reordered

## Getting Phrases

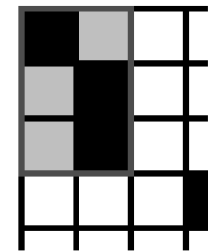

## Extracting Phrase Pairs

	michael	geht	davon	aus	,	dass	er	im	haus	bleibt
michael	■									
assumes		■	■	■	■	■				
that		■	■	■	■	■				
he							■			
will										■
stay										■
in								■		
the								■		
house									■	

extract phrase pair consistent with word alignment:

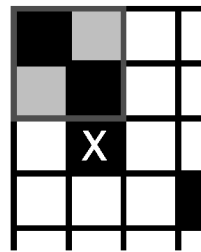

assumes that / geht davon aus , dass

## Consistent

consistent

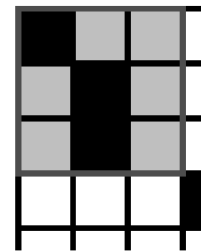

**ok**

inconsistent

**violated**

one  
alignment  
point outside

consistent

**ok**

unaligned  
word is fine

All words of the phrase pair have to align to each other.

## Phrase Pair Extraction

	michael	geht	davon	aus	,	dass	er	im	haus	bleibt
michael	■									
assumes		■	■	■						
that						■				
he							■			
will										■
stay										■
in								■		
the								■		
house									■	

Smallest phrase pairs:

michael — michael

assumes — geht davon aus / geht davon aus ,

that — dass / , dass

he — er

will stay — bleibt

in the — im

house — haus

unaligned words (here: German comma) lead to multiple translations

## Larger Phrase Pairs

	michael	geht	davon	aus	,	dass	er	im	haus	bleibt
michael										
assumes										
that										
he										
will										
stay										
in										
the										
house										

michael assumes — michael geht davon aus / michael geht davon aus ,  
 assumes that — geht davon aus , dass ; assumes that he — geht davon aus , dass er  
 that he — dass er / , dass er ; in the house — im haus  
 michael assumes that — michael geht davon aus , dass  
 michael assumes that he — michael geht davon aus , dass er  
 michael assumes that he will stay in the house — michael geht davon aus , dass er im haus bleibt  
 assumes that he will stay in the house — geht davon aus , dass er im haus bleibt  
 that he will stay in the house — dass er im haus bleibt ; dass er im haus bleibt ,  
 he will stay in the house — er im haus bleibt ; will stay in the house — im haus bleibt

## Scoring Phrase Translations

- Phrase pair extraction: collect all phrase pairs from the data
- Phrase pair scoring: assign probabilities to phrase translations
- Score by relative frequency:

$$\phi(\bar{f}|\bar{e}) = \frac{\text{count}(\bar{e}, \bar{f})}{\sum_{\bar{f}_i} \text{count}(\bar{e}, \bar{f}_i)}$$

## Real Example

- Phrase translations for *den Vorschlag* learned from the Europarl corpus:

English	$\phi(\bar{e} f)$	English	$\phi(\bar{e} f)$
the proposal	0.6227	the suggestions	0.0114
's proposal	0.1068	the proposed	0.0114
a proposal	0.0341	the motion	0.0091
the idea	0.0250	the idea of	0.0091
this proposal	0.0227	the proposal ,	0.0068
proposal	0.0205	its proposal	0.0068
of the proposal	0.0159	it	0.0068
the proposals	0.0159	...	...

- lexical variation (*proposal* vs *suggestions*)
- morphological variation (*proposal* vs *proposals*)
- included function words (*the*, *a*, ...)
- noise (*it*)

## Other Scoring Terms

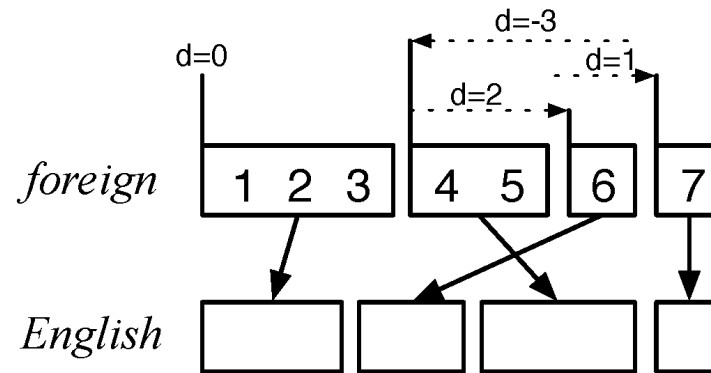

## More Feature Functions

- Bidirectional alignment probabilities:  $\phi(\bar{e}|\bar{f})$  and  $\phi(\bar{f}|\bar{e})$
- Rare phrase pairs have unreliable phrase translation probability estimates  
→ lexical weighting with word translation probabilities

	geht	nicht	davon	aus	NULL
does					
not					
assume					

$$\text{lex}(\bar{e}|\bar{f}, a) = \prod_{i=1}^{\text{length}(\bar{e})} \frac{1}{|\{j | (i, j) \in a\}|} \sum_{\forall (i, j) \in a} w(e_i | f_j)$$

## Distance-Based Reordering

phrase	translates	movement	distance
1	1–3	start at beginning	0
2	6	skip over 4–5	+2
3	4–5	move back over 4–6	-3
4	7	skip over 6	+1

Scoring function:  $d(x) = \alpha^{|x|}$  — exponential with distance

## Phrase-Based Decoding

## Translation Options

er	geht	ja	nicht	nach	hause
he	is	yes	not	after	house
it	are	is	do not	to	home
, it	goes	, of course	does not	according to	chamber
, he	go	,	is not	in	at home
it is		not		home	
he will be		is not		under house	
it goes		does not		return home	
he goes		do not		do not	
	is		to		
	are		following		
	is after all		not after		
	does		not to		
	not				
	is not				
	are not				
	is not a				

- Many translation options to choose from
  - in Europarl phrase table: 2727 matching phrase pairs for this sentence
  - by pruning to the top 20 per phrase, 202 translation options remain

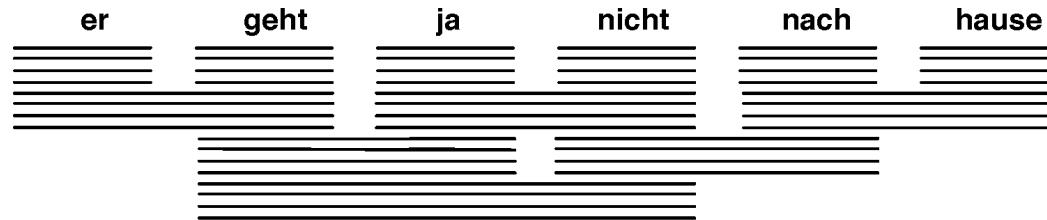

## Translation Options

er	geht	ja	nicht	nach	hause
he	is	yes	not	after	house
it	are	is	do not	to	home
, it	goes	, of course	does not	according to	chamber
, he	go		is not	in	at home
it is		not		home	
he will be		is not		under house	
it goes		does not		return home	
he goes		do not		do not	
	is		to		
	are		following		
	is after all		not after		
	does		not to		
	not				
	is not				
	are not				
	is not a				

- The machine translation decoder does not know the right answer
  - picking the right translation options
  - arranging them in the right order

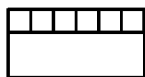

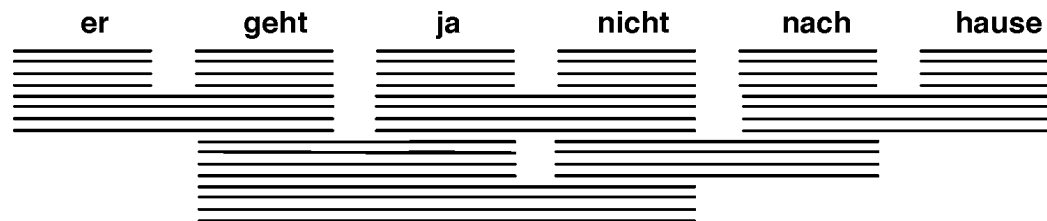

→ Search problem solved by heuristic beam search

## Decoding: Precompute Translation Options

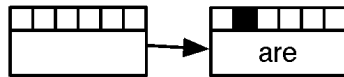

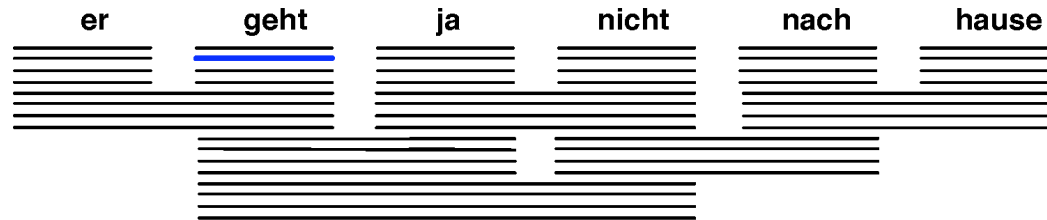

consult phrase translation table for all input phrases

## Decoding: Start with Initial Hypothesis

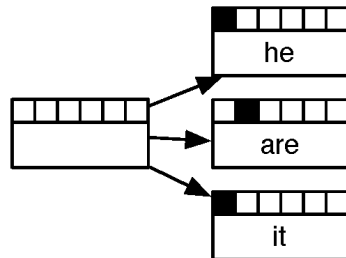

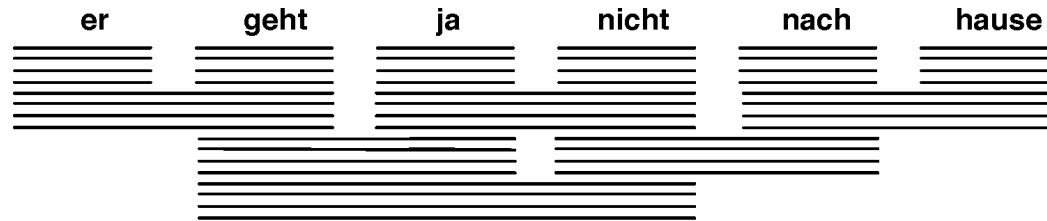

initial hypothesis: no input words covered, no output produced

## Decoding: Hypothesis Expansion

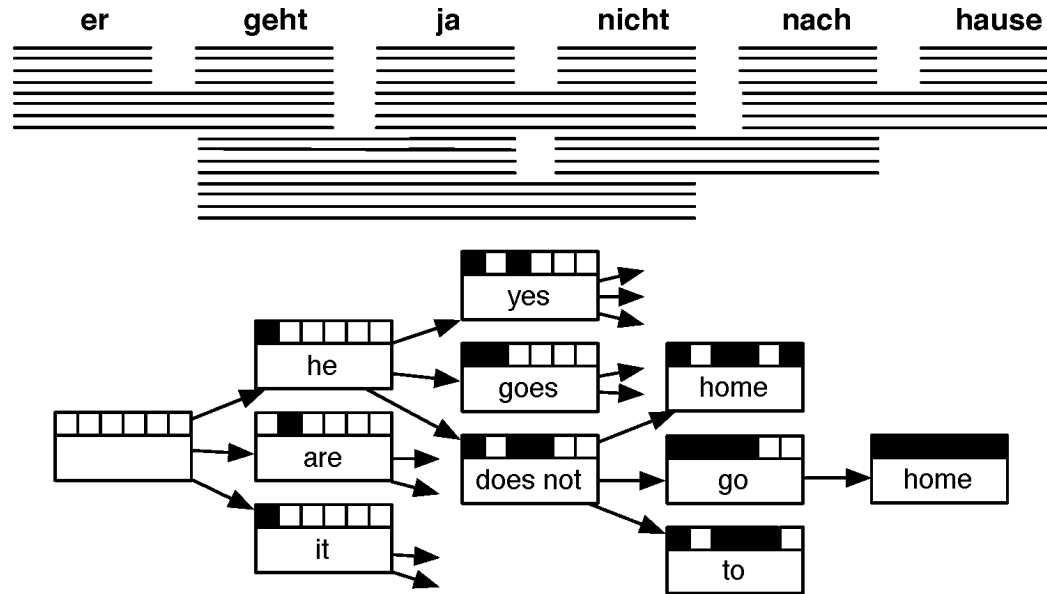

pick any translation option, create new hypothesis

## Decoding: Hypothesis Expansion

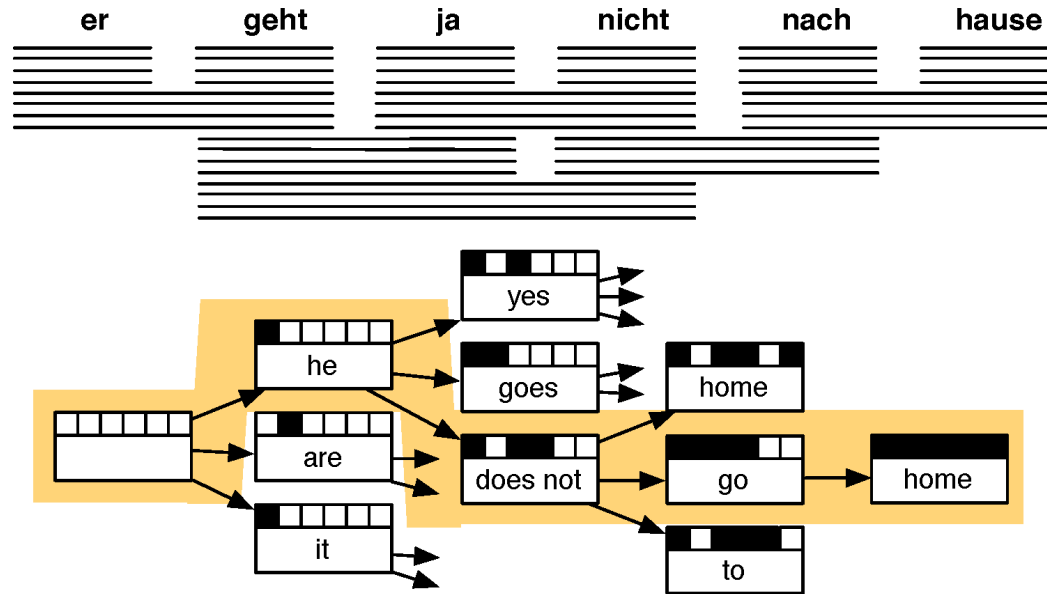

create hypotheses for all other translation options

## Decoding: Hypothesis Expansion

also create hypotheses from created partial hypothesis

## Decoding: Find Best Path

backtrack from highest scoring complete hypothesis

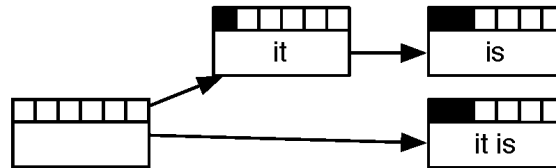

# Dynamic Programming

## Computational Complexity

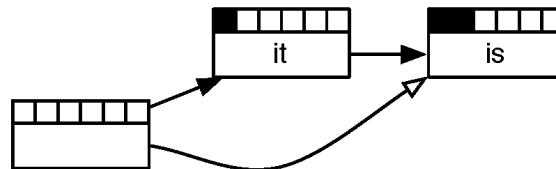

- The suggested process creates exponential number of hypothesis
- Machine translation decoding is NP-complete
- Reduction of search space:
  - recombination (risk-free)
  - pruning (risky)

## Recombination

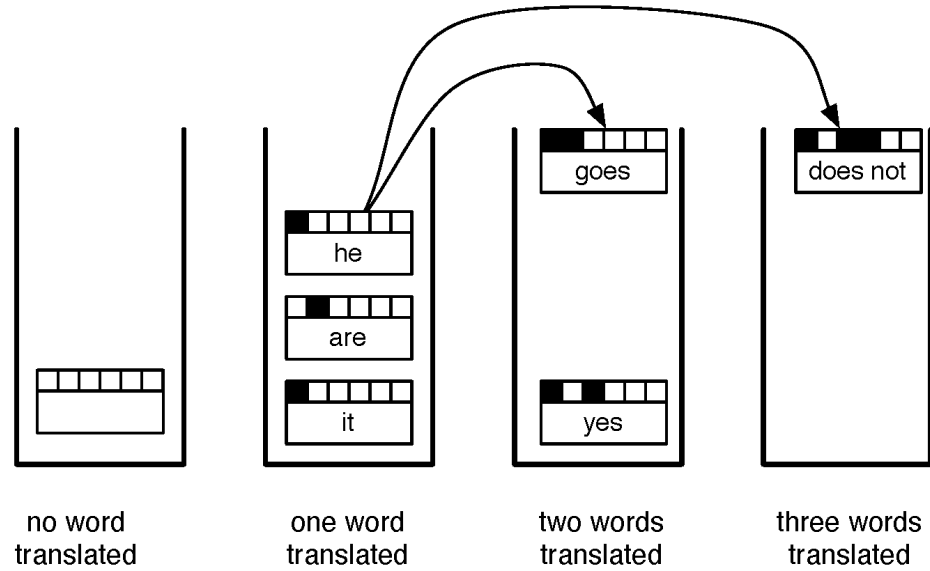

- Two hypothesis paths lead to two matching hypotheses
  - same foreign words translated
  - same English words in the output

- Worse hypothesis is dropped

## Stacks

- Hypothesis expansion in a stack decoder
  - translation option is applied to hypothesis
  - new hypothesis is dropped into a stack further down

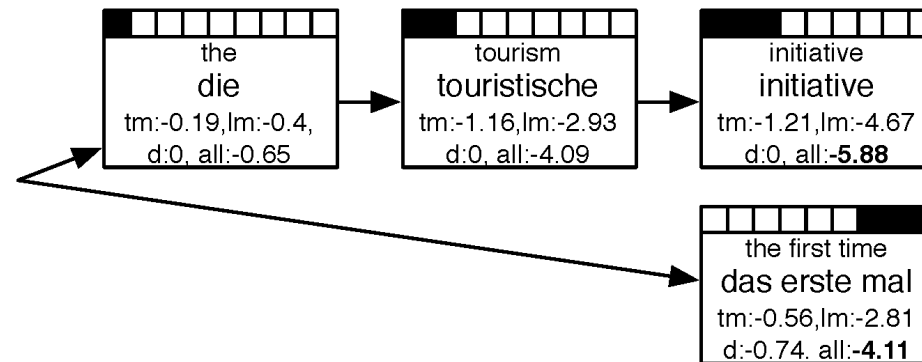

## Stack Decoding Algorithm

```
1: place empty hypothesis into stack 0
2: for all stacks  $0 \dots n - 1$  do
3:   for all hypotheses in stack do
4:     for all translation options do
5:       if applicable then
6:         create new hypothesis
7:         place in stack
8:         recombine with existing hypothesis if possible
9:         prune stack if too big
10:      end if
11:    end for
12:  end for
13: end for
```

Future Costs

## Translating the Easy Part First?

the tourism initiative addresses this for the first time

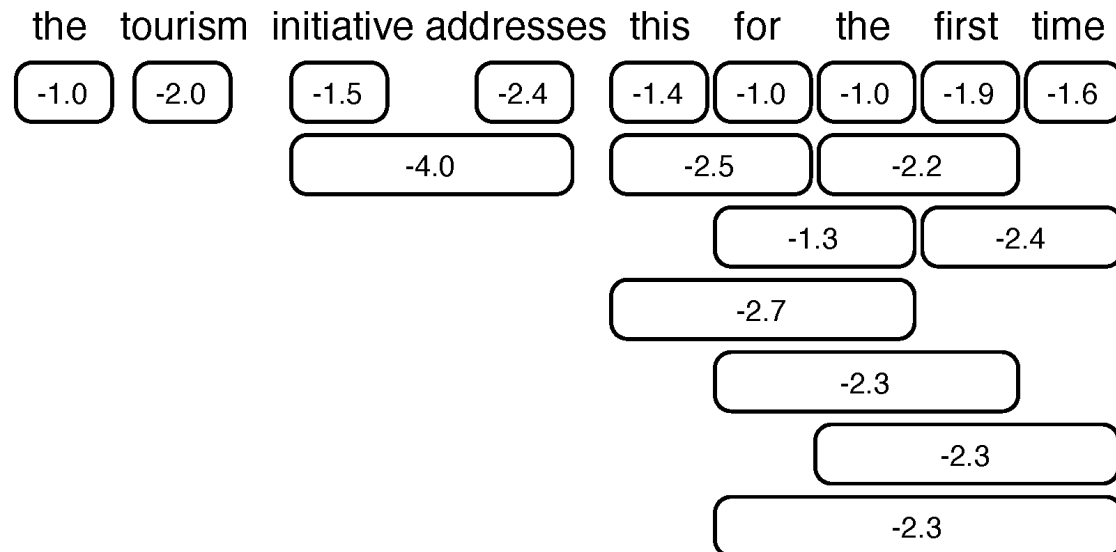

both hypotheses translate 3 words  
worse hypothesis has better score

## Estimating Future Cost

- Future cost estimate: how expensive is translation of rest of sentence?
- Optimistic: choose cheapest translation options
- Cost for each translation option
  - **translation model**: cost known
  - **language model**: output words known, but not context  
→ estimate without context
  - **reordering model**: unknown, ignored for future cost estimation

## Cost Estimates from Translation Options

cost of cheapest translation options for each input span (log-probabilities)

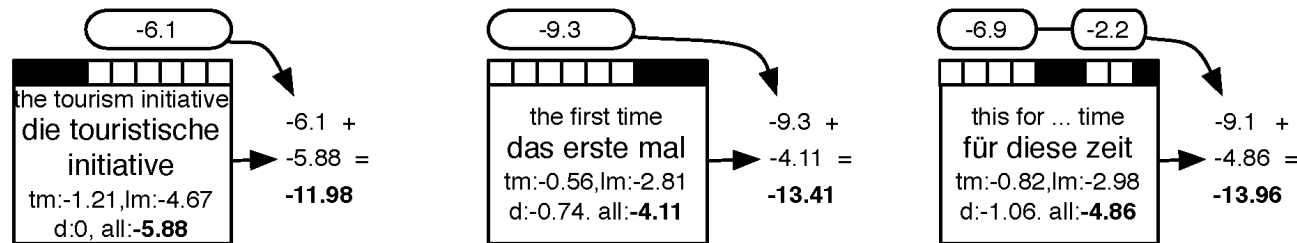

## Cost Estimates for all Spans

- Compute cost estimate for all contiguous spans by combining cheapest options

first word	future cost estimate for $n$ words (from first)								
	1	2	3	4	5	6	7	8	9
the	-1.0	-3.0	-4.5	-6.9	-8.3	-9.3	-9.6	-10.6	-10.6
tourism	-2.0	-3.5	-5.9	-7.3	-8.3	-8.6	-9.6	-9.6	
initiative	-1.5	-3.9	-5.3	-6.3	-6.6	-7.6	-7.6		
addresses	-2.4	-3.8	-4.8	-5.1	-6.1	-6.1			
this	-1.4	-2.4	-2.7	-3.7	-3.7				
for	-1.0	-1.3	-2.3	-2.3					
the	-1.0	-2.2	-2.3						
first	-1.9	-2.4							
time	-1.6								

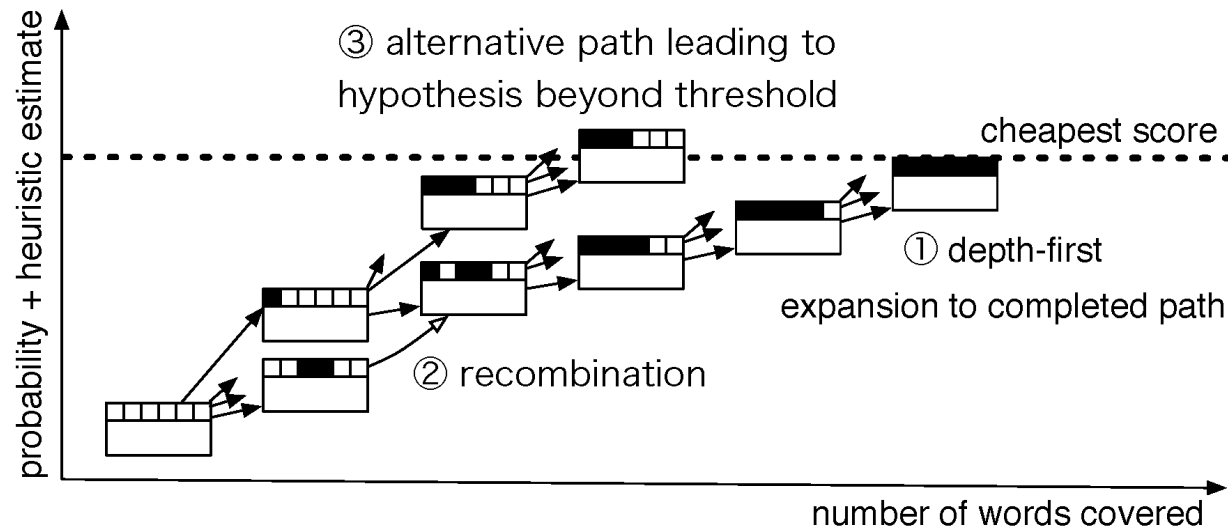

- Function words cheaper (the: -1.0) than content words (tourism -2.0)
- Common phrases cheaper (for the first time: -2.3) than unusual ones (tourism initiative addresses: -5.9)

## Combining Score and Future Cost

- Hypothesis score and future cost estimate are combined for pruning
  - left hypothesis starts with hard part: **the tourism initiative**  
score: -5.88, future cost: -6.1 → total cost -11.98
  - middle hypothesis starts with easiest part: **the first time**  
score: -4.11, future cost: -9.3 → total cost -13.41
  - right hypothesis picks easy parts: **this for ... time**  
score: -4.86, future cost: -9.1 → total cost -13.96

## A\* Search

- Uses *admissible* future cost heuristic: never overestimates cost
- Translation agenda: create hypothesis with lowest score + heuristic cost
- Done, when complete hypothesis created

## 1990s-2010s: Statistical Machine Translation

- SMT was a huge research field
- The best systems were extremely complex
  - Hundreds of important details we haven't mentioned here
  - Systems had many separately-designed subcomponents
  - Lots of feature engineering
    - Need to design features to capture particular language phenomena
  - Require compiling and maintaining extra resources
    - Like tables of equivalent phrases
  - Lots of human effort to maintain
    - Repeated effort for each language pair!

# Neural Machine Translation

2014

Neural  
Machine  
Translation

MT research

(dramatic reenactment)

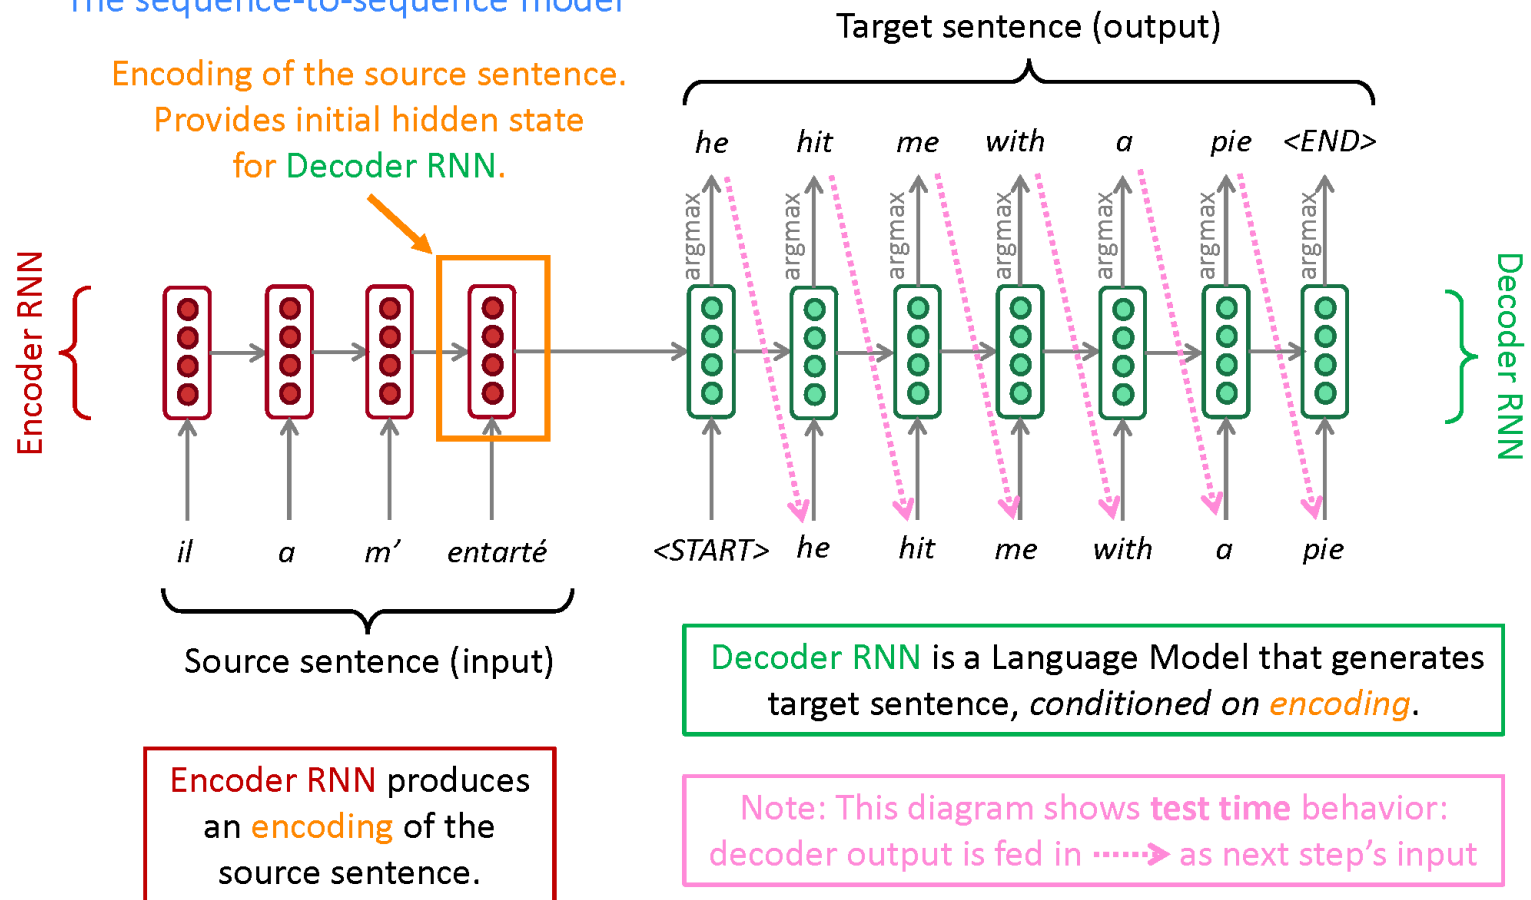

## What is Neural Machine Translation?

- Neural Machine Translation (NMT) is a way to do Machine Translation with a *single neural network*
- The neural network architecture is called *sequence-to-sequence* (aka *seq2seq*) and it involves *two* RNNs.

# Neural Machine Translation (NMT)

The sequence-to-sequence model

## Sequence-to-sequence is versatile!

- Sequence-to-sequence is useful for *more than just MT*
- Many NLP tasks can be phrased as sequence-to-sequence:
  - **Summarization** (long text → short text)
  - **Dialogue** (previous utterances → next utterance)
  - **Parsing** (input text → output parse as sequence)
  - **Code generation** (natural language → Python code)

# Neural Machine Translation (NMT)

- The **sequence-to-sequence** model is an example of a **Conditional Language Model**.
  - **Language Model** because the decoder is predicting the next word of the target sentence  $y$
  - **Conditional** because its predictions are *also* conditioned on the source sentence  $x$

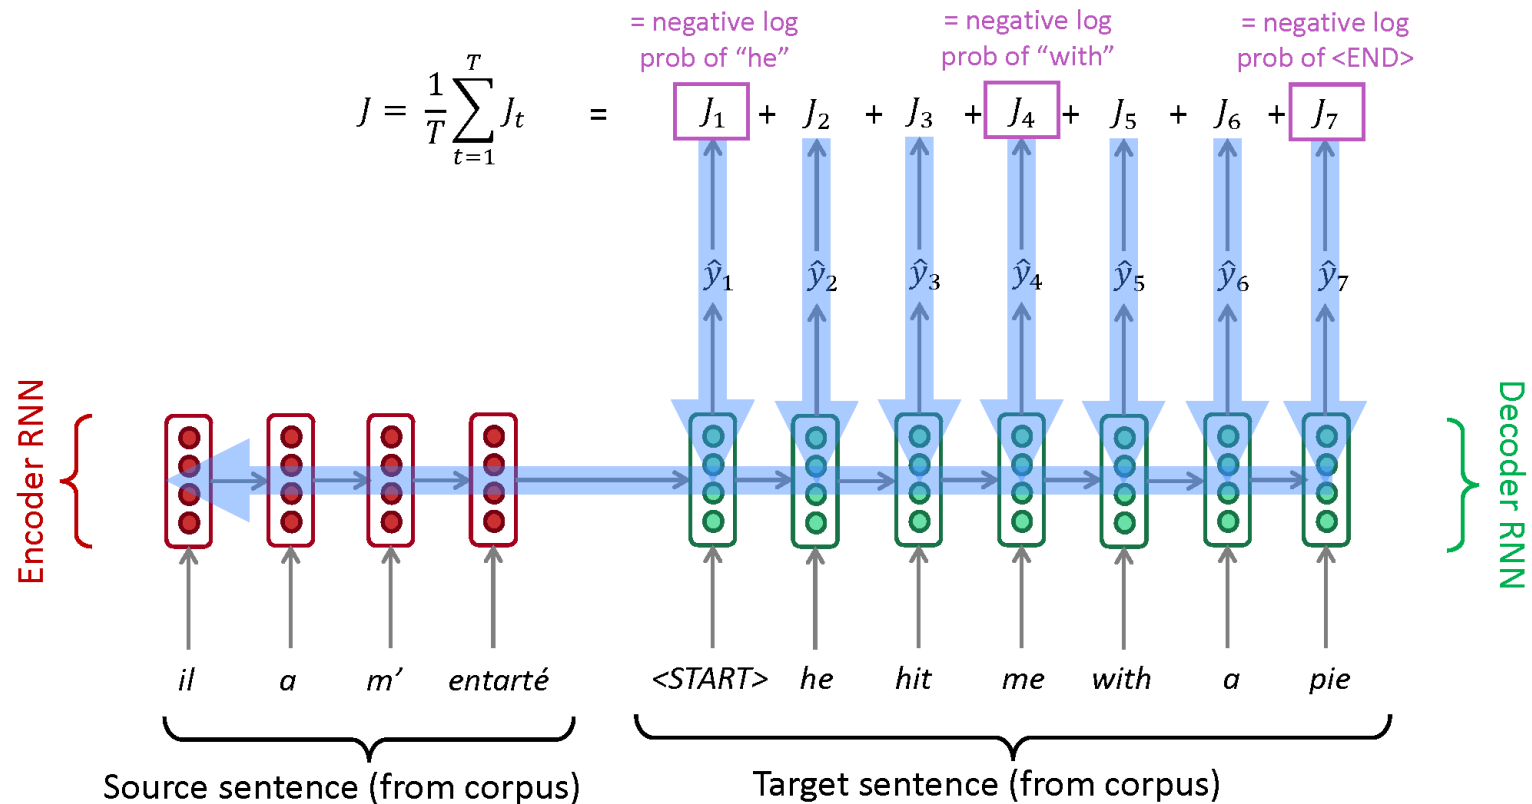

- NMT directly calculates  $P(y|x)$ :

$$P(y|x) = P(y_1|x) P(y_2|y_1, x) P(y_3|y_1, y_2, x) \dots \underbrace{P(y_T|y_1, \dots, y_{T-1}, x)}$$

Probability of next target word, given target words so far and source sentence  $x$

- **Question:** How to **train** a NMT system?
- **Answer:** Get a big parallel corpus...

# Training a Neural Machine Translation system

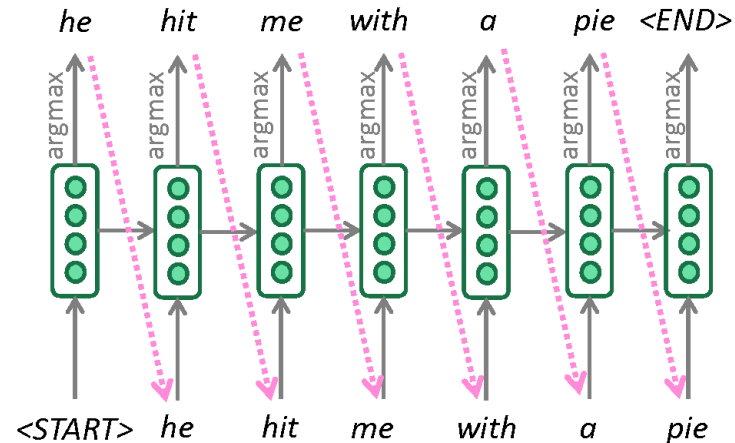

Seq2seq is optimized as a single system.  
Backpropagation operates "*end-to-end*".

## NMT Decoding

## Greedy decoding

- We saw how to generate (or “decode”) the target sentence by taking argmax on each step of the decoder

- This is **greedy decoding** (take most probable word on each step)
- **Problems with this method?**

## Problems with greedy decoding

- Greedy decoding has no way to undo decisions!
  - Input: *il a m'entarté*      (*he hit me with a pie*)
  - → *he* \_\_\_\_\_
  - → *he hit* \_\_\_\_\_
  - → *he hit a* \_\_\_\_\_      (whoops! no going back now...)
- How to fix this?

## Exhaustive search decoding

- Ideally we want to find a (length  $T$ ) translation  $y$  that maximizes

$$\begin{aligned} P(y|x) &= P(y_1|x) P(y_2|y_1, x) P(y_3|y_1, y_2, x) \dots, P(y_T|y_1, \dots, y_{T-1}, x) \\ &= \prod_{t=1}^T P(y_t|y_1, \dots, y_{t-1}, x) \end{aligned}$$

- We could try computing **all possible sequences  $y$** 
  - This means that on each step  $t$  of the decoder, we're tracking  $V^t$  possible partial translations, where  $V$  is vocab size
  - This  $O(V^T)$  complexity is **far too expensive!**

## Beam search decoding

- Core idea: On each step of decoder, keep track of the *k* most probable partial translations (which we call *hypotheses*)
  - *k* is the beam size (in practice around 5 to 10)
- A hypothesis  $y_1, \dots, y_t$  has a score which is its log probability:
$$\text{score}(y_1, \dots, y_t) = \log P_{\text{LM}}(y_1, \dots, y_t | x) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$$
  - Scores are all negative, and higher score is better
  - We search for high-scoring hypotheses, tracking top *k* on each step
- Beam search is *not guaranteed* to find optimal solution
- But *much more efficient* than exhaustive search!

## Beam search decoding: example

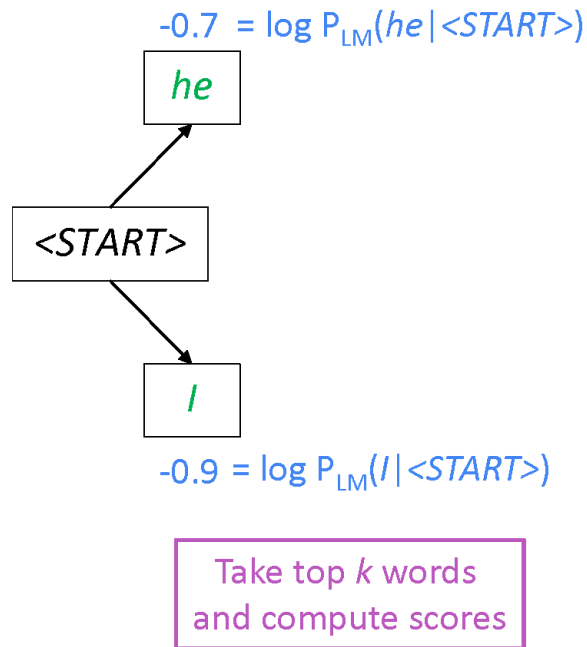

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

<START>

Calculate prob  
dist of next word

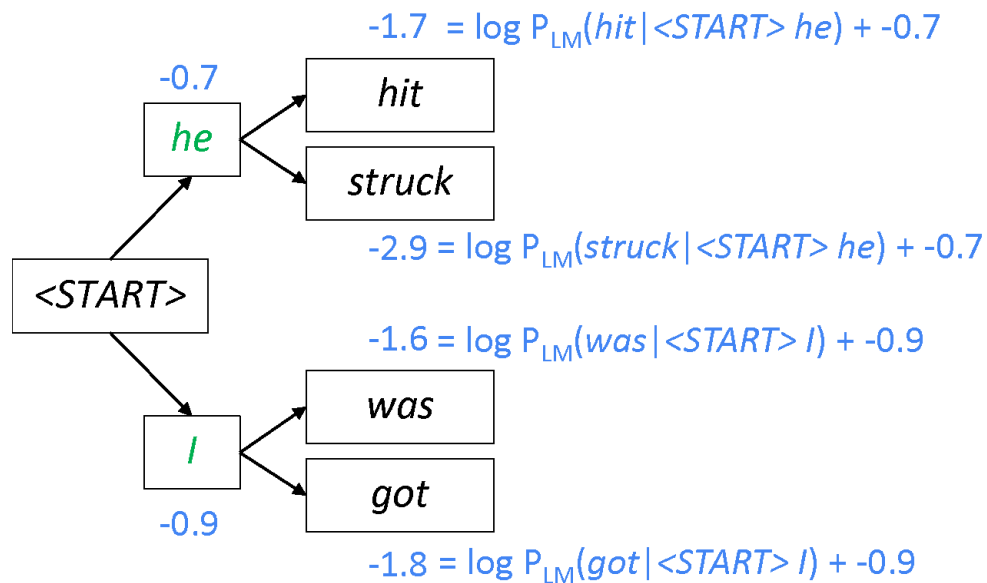

## Beam search decoding: example

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

## Beam search decoding: example

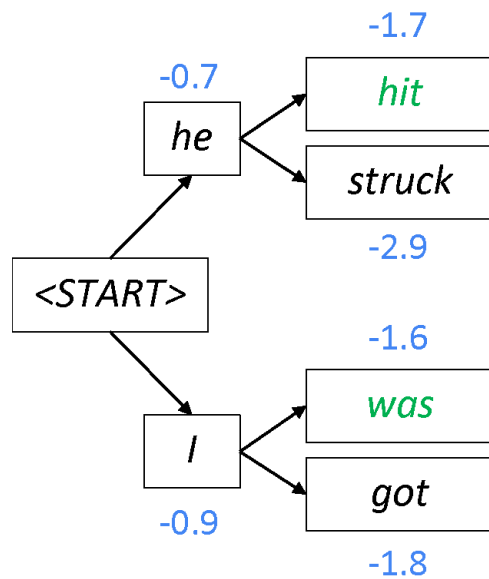

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

For each of the  $k$  hypotheses, find top  $k$  next words and calculate scores

## Beam search decoding: example

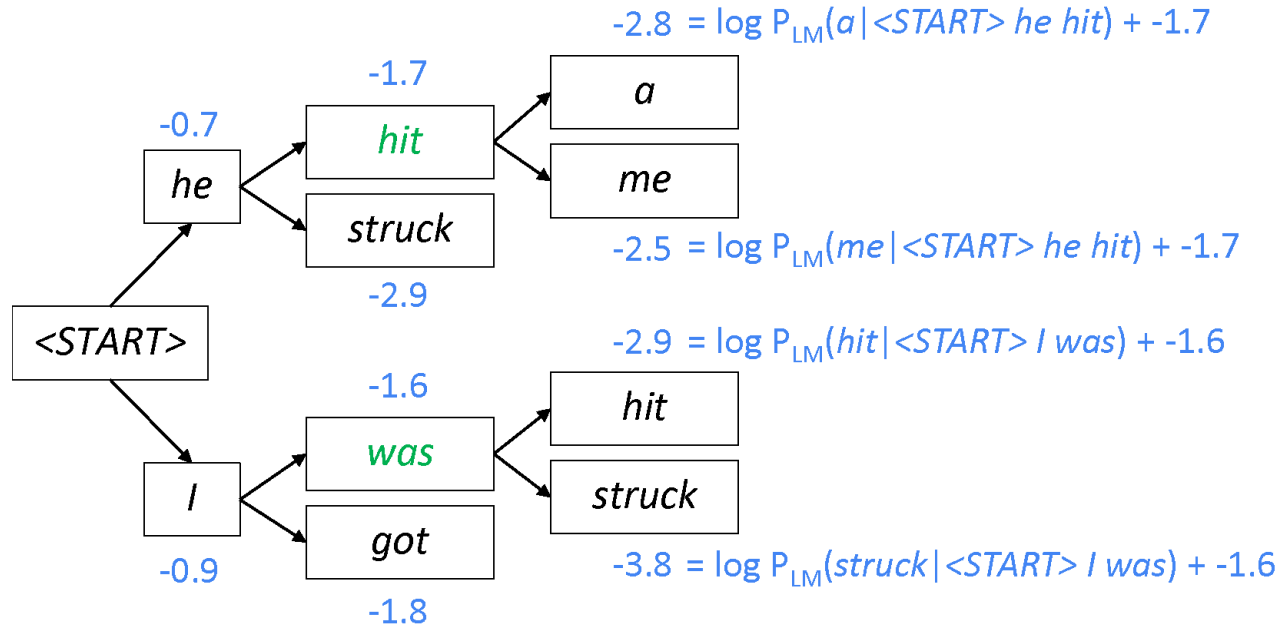

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

Of these  $k^2$  hypotheses,  
just keep  $k$  with highest scores

## Beam search decoding: example

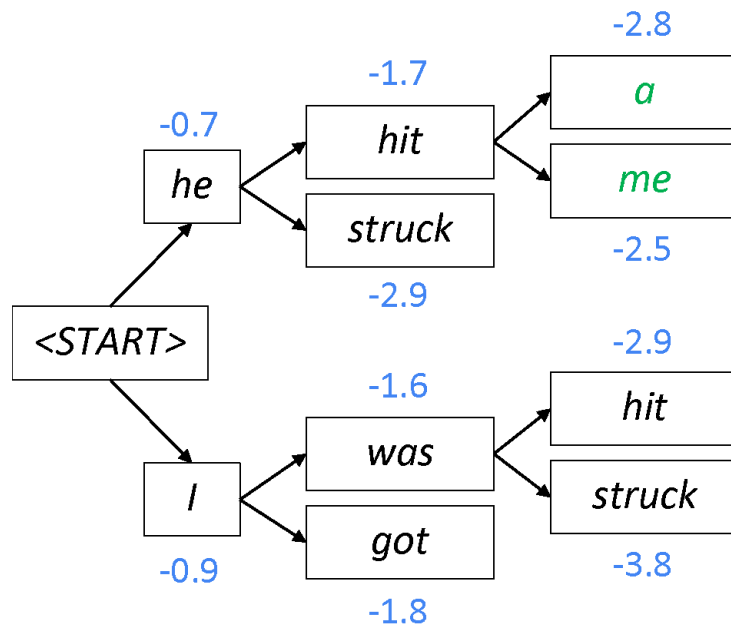

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

For each of the  $k$  hypotheses, find top  $k$  next words and calculate scores

## Beam search decoding: example

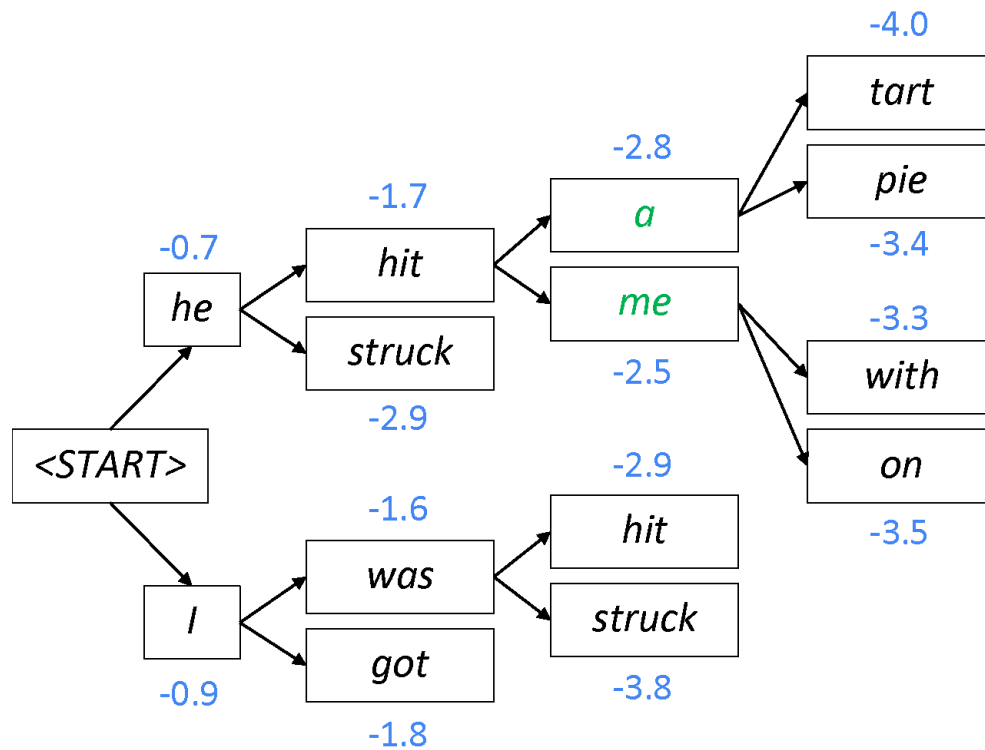

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

Of these  $k^2$  hypotheses,  
just keep  $k$  with highest scores

## Beam search decoding: example

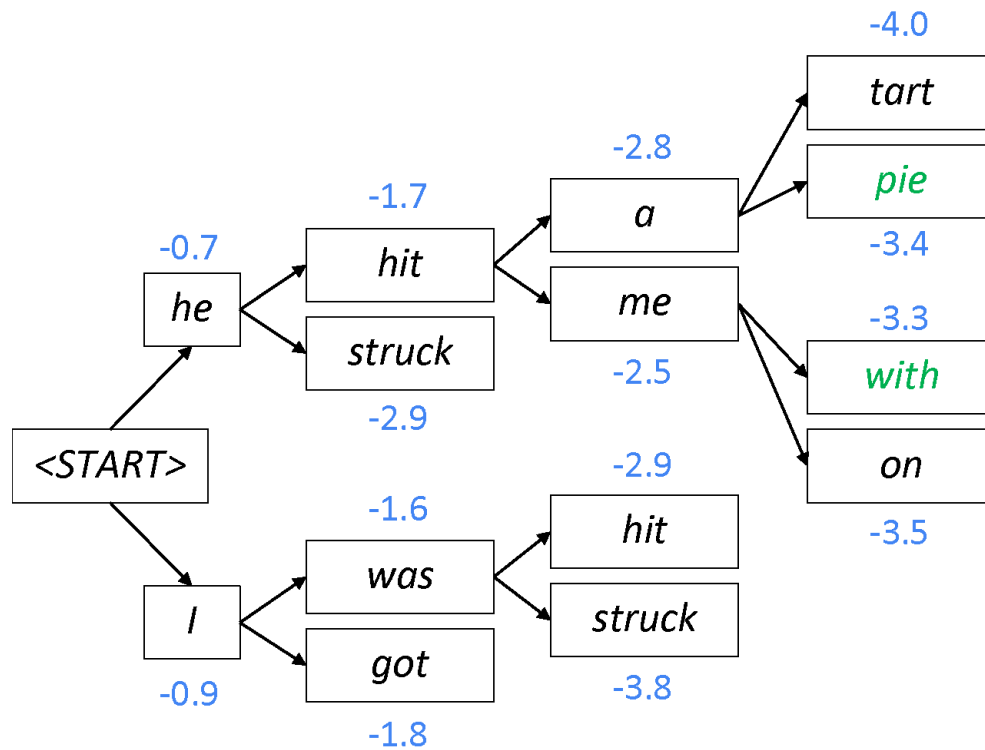

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

For each of the  $k$  hypotheses, find top  $k$  next words and calculate scores

## Beam search decoding: example

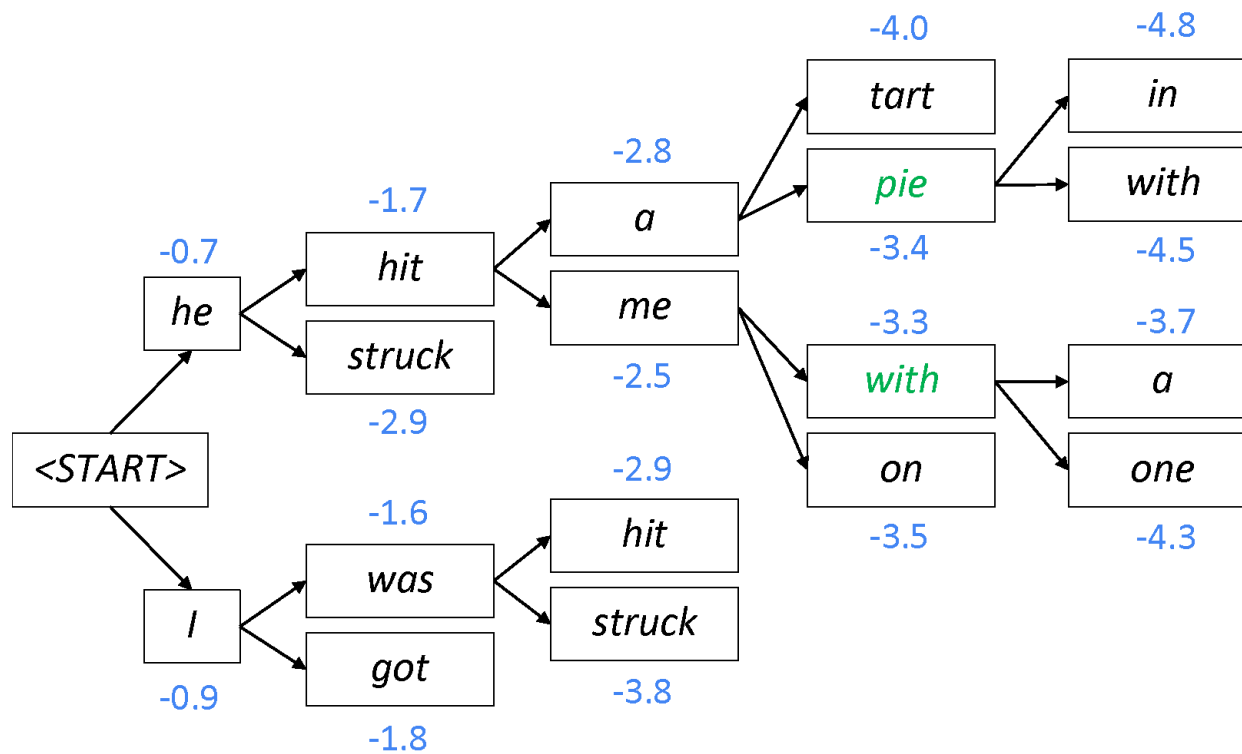

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

Of these  $k^2$  hypotheses,  
just keep  $k$  with highest scores

## Beam search decoding: example

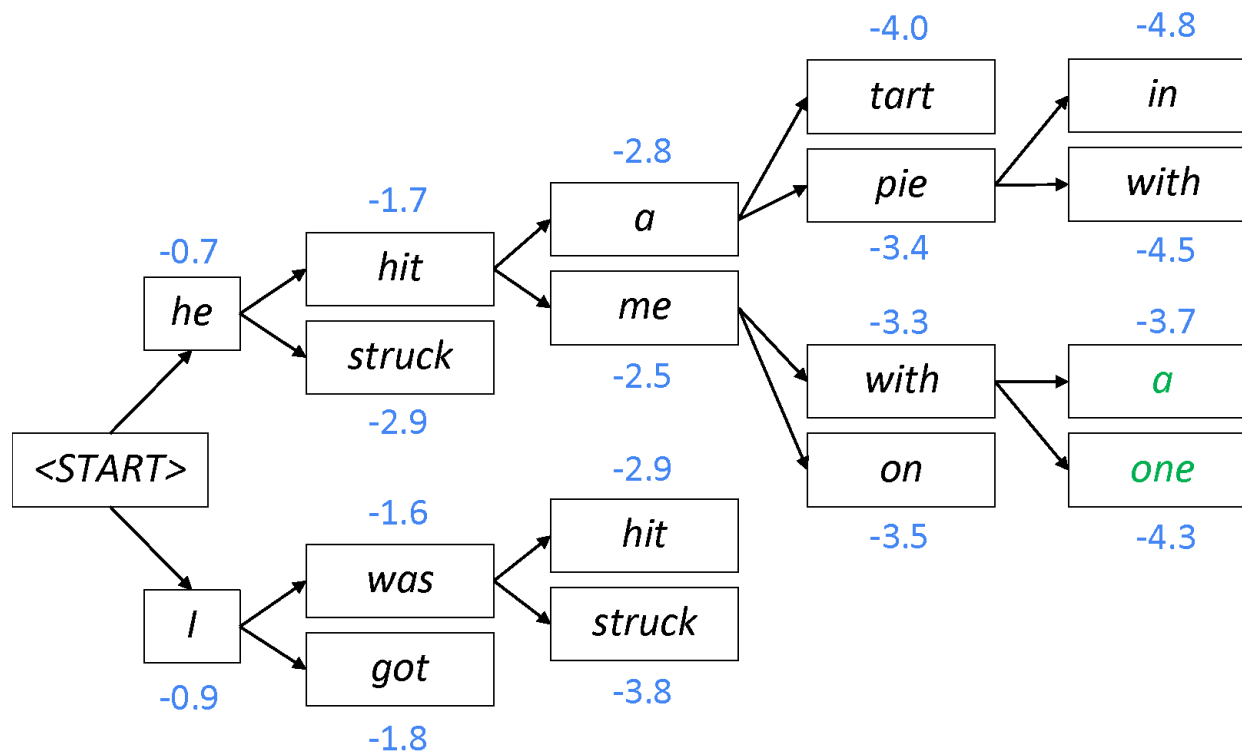

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

For each of the  $k$  hypotheses, find top  $k$  next words and calculate scores

## Beam search decoding: example

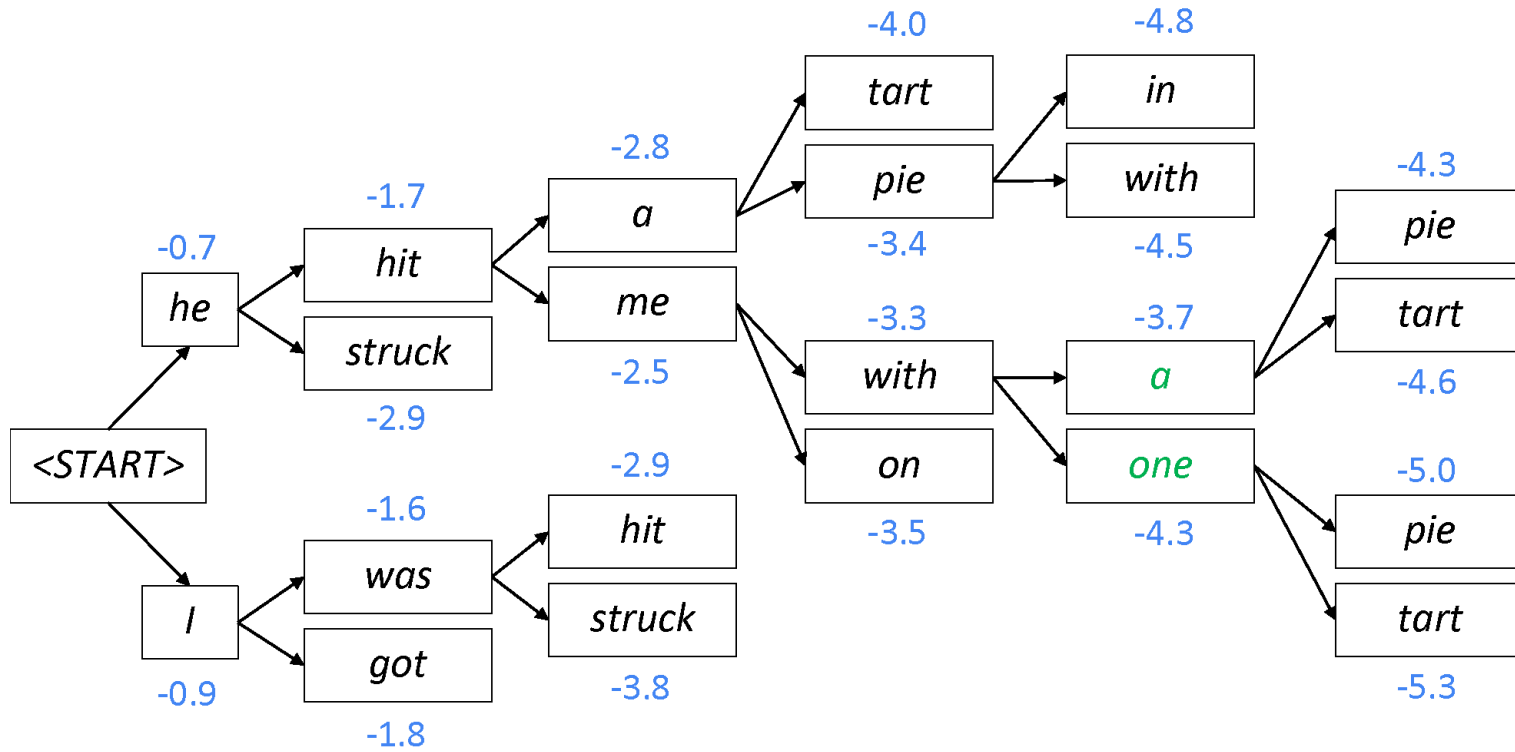

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

Of these  $k^2$  hypotheses,  
just keep  $k$  with highest scores

## Beam search decoding: example

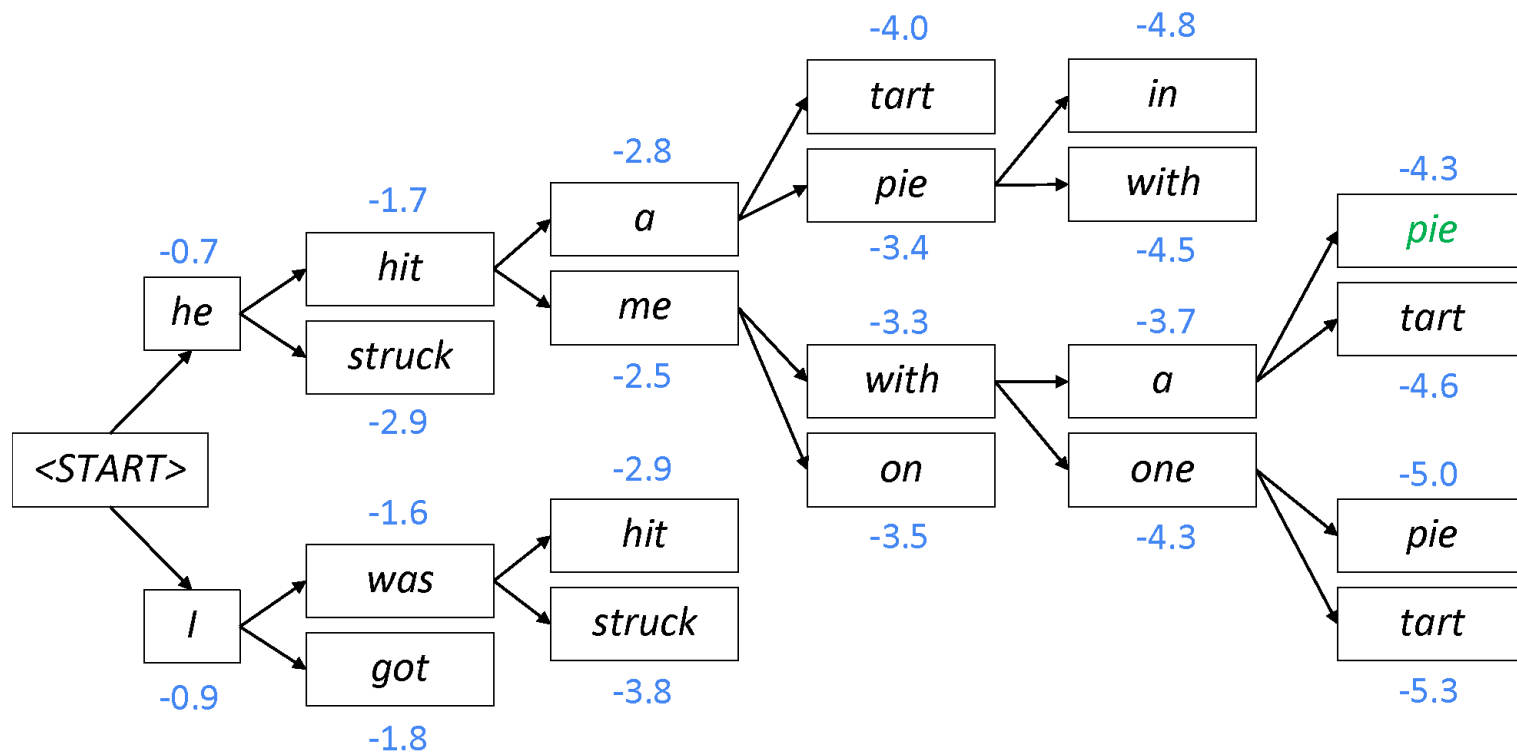

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

For each of the  $k$  hypotheses, find top  $k$  next words and calculate scores

## Beam search decoding: example

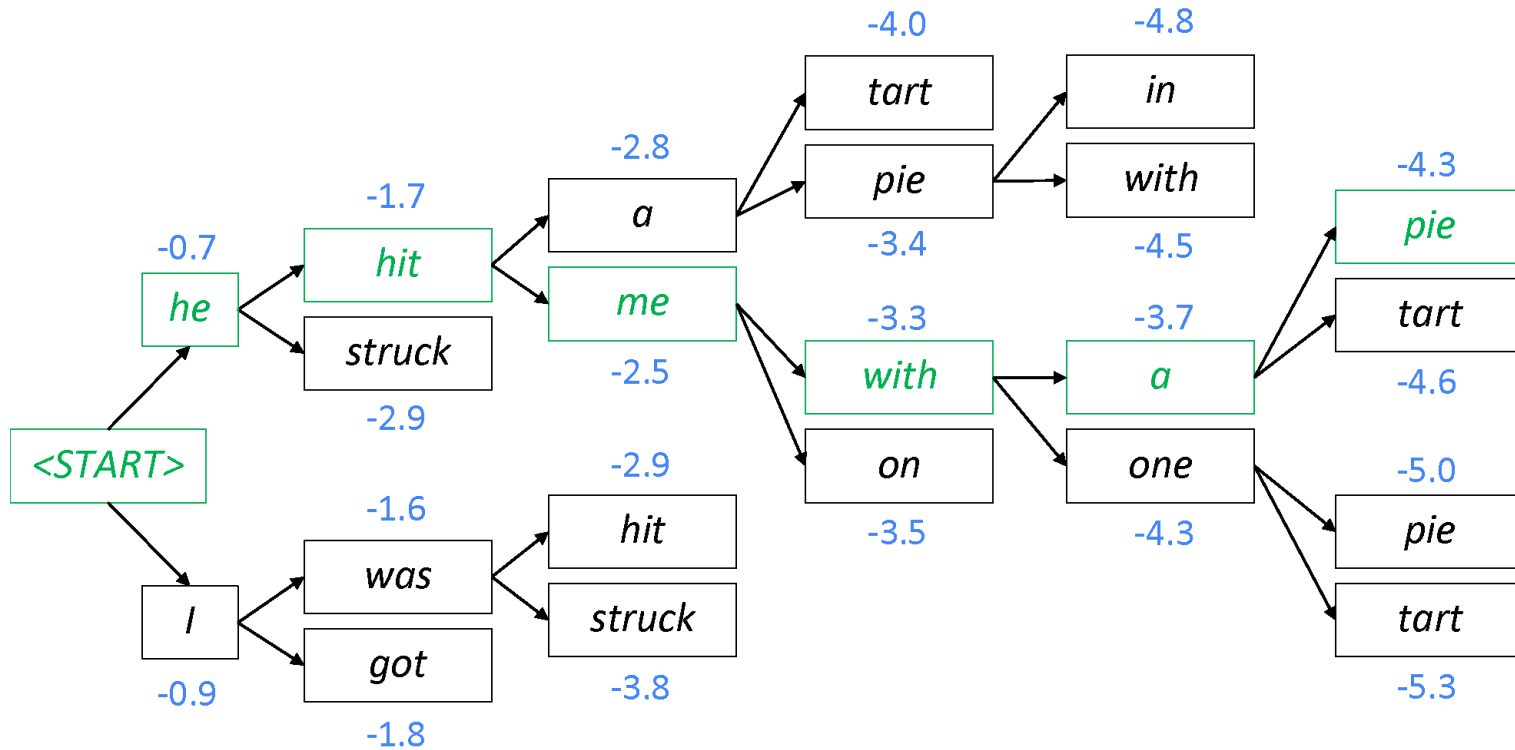

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

This is the top-scoring hypothesis!

## Beam search decoding: example

Beam size =  $k = 2$ . Blue numbers =  $\text{score}(y_1, \dots, y_t) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$

Backtrack to obtain the full hypothesis

## Beam search decoding: stopping criterion

- In **greedy decoding**, usually we decode until the model produces a **<END> token**
  - For example: *<START> he hit me with a pie <END>*
- In **beam search decoding**, different hypotheses may produce **<END> tokens on different timesteps**
  - When a hypothesis produces **<END>**, that hypothesis is **complete**.
  - **Place it aside** and continue exploring other hypotheses via beam search.
- Usually we continue beam search until:
  - We reach timestep  $T$  (where  $T$  is some pre-defined cutoff), or
  - We have at least  $n$  completed hypotheses (where  $n$  is pre-defined cutoff)

## Beam search decoding: finishing up

- We have our list of completed hypotheses.
- How to select top one with highest score?
- Each hypothesis  $y_1, \dots, y_t$  on our list has a score

$$\text{score}(y_1, \dots, y_t) = \log P_{\text{LM}}(y_1, \dots, y_t | x) = \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$$

- Problem with this: longer hypotheses have lower scores
- Fix: Normalize by length. Use this to select top one instead:

$$\frac{1}{t} \sum_{i=1}^t \log P_{\text{LM}}(y_i | y_1, \dots, y_{i-1}, x)$$

Attention

## Sequence-to-sequence: the bottleneck problem

Problems with this architecture?

# Sequence-to-sequence: the bottleneck problem

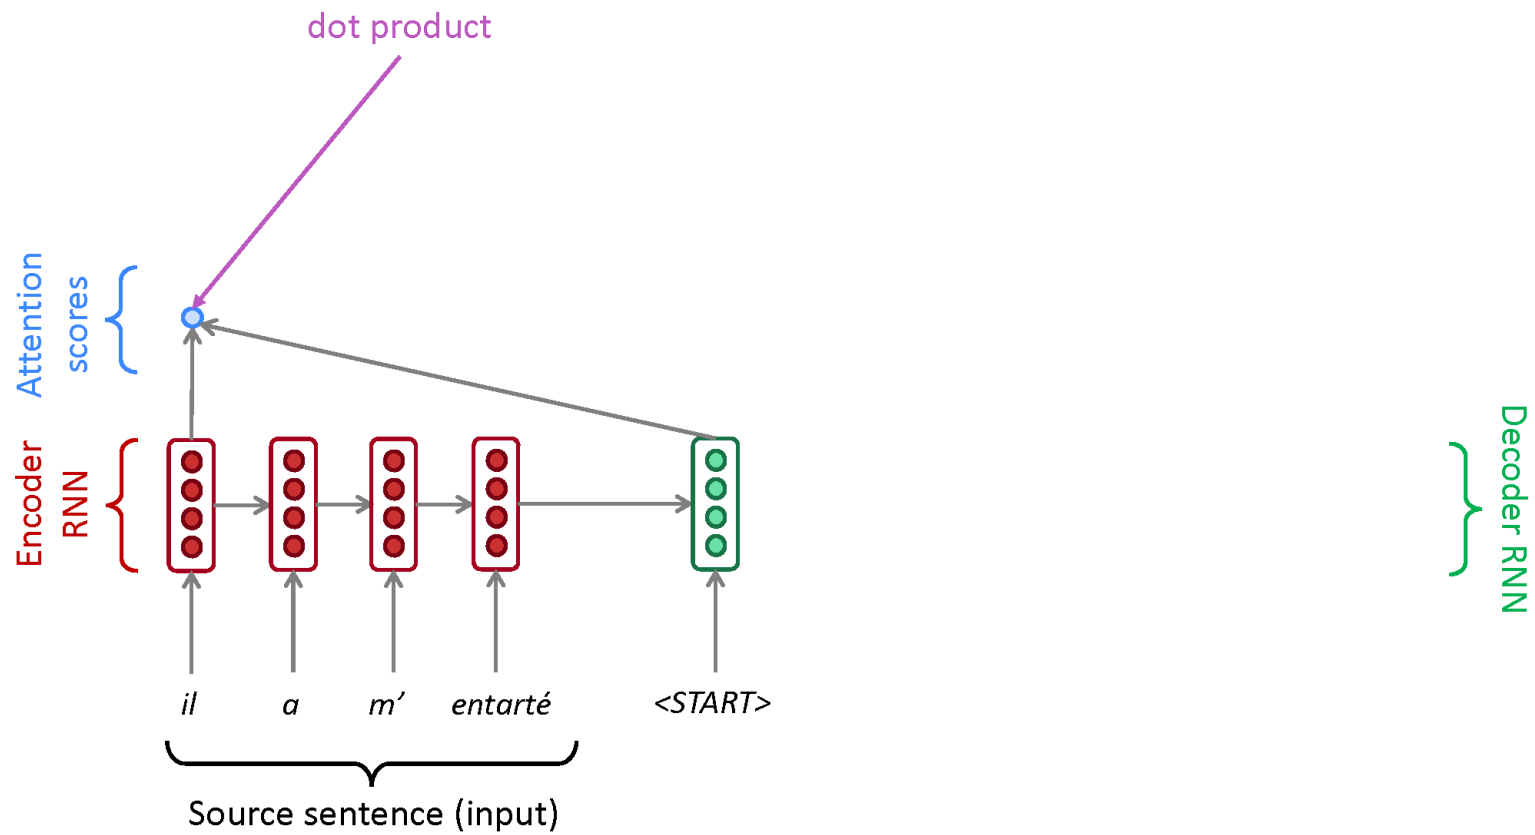

# Attention

- **Attention** provides a solution to the bottleneck problem.
- Core idea: on each step of the decoder, use *direct connection to the encoder* to *focus on a particular part* of the source sequence

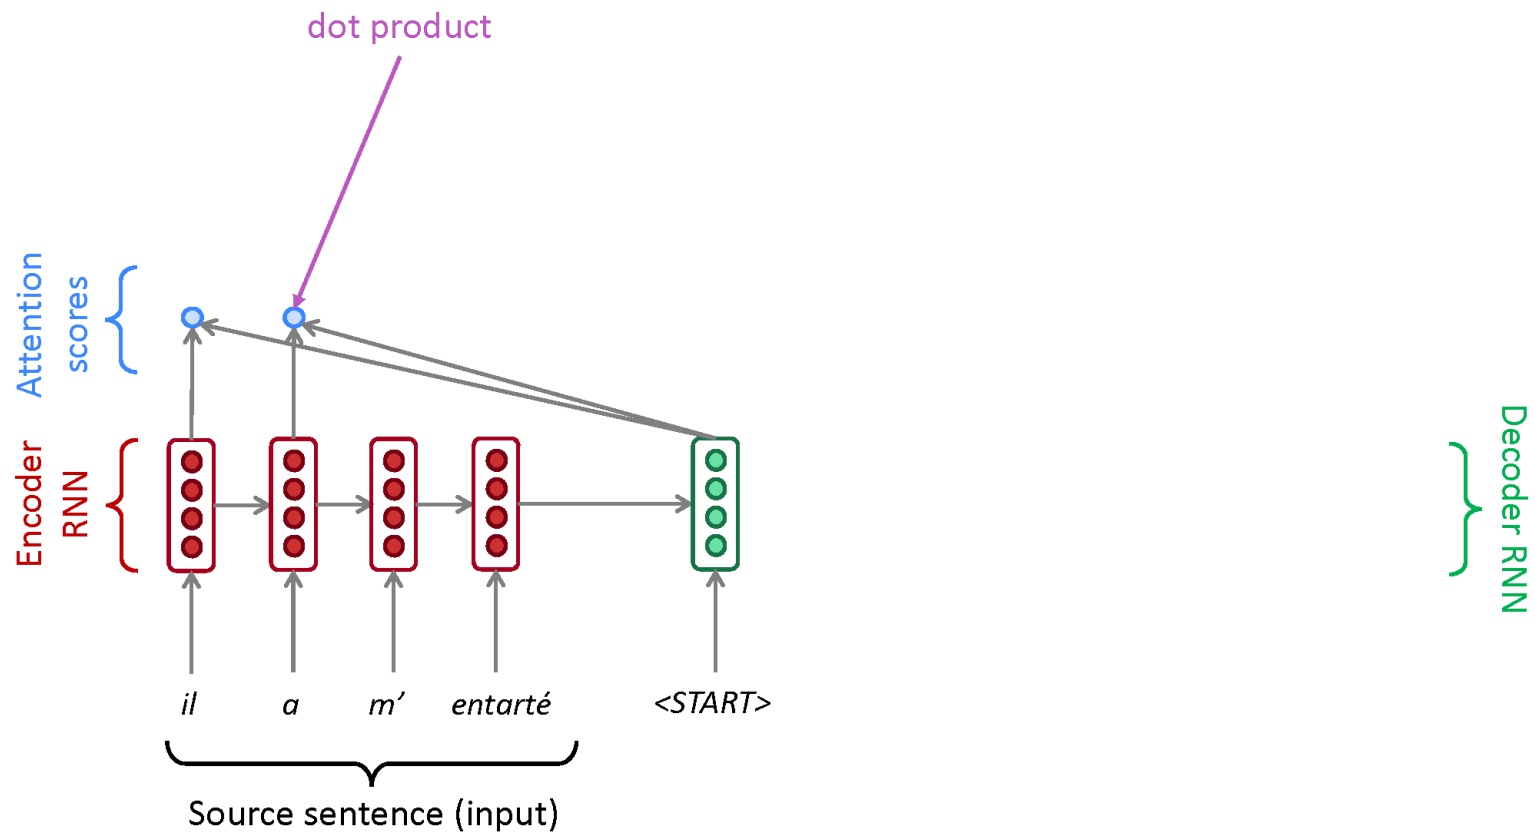

- First we will show via diagram (no equations), then we will show with equations

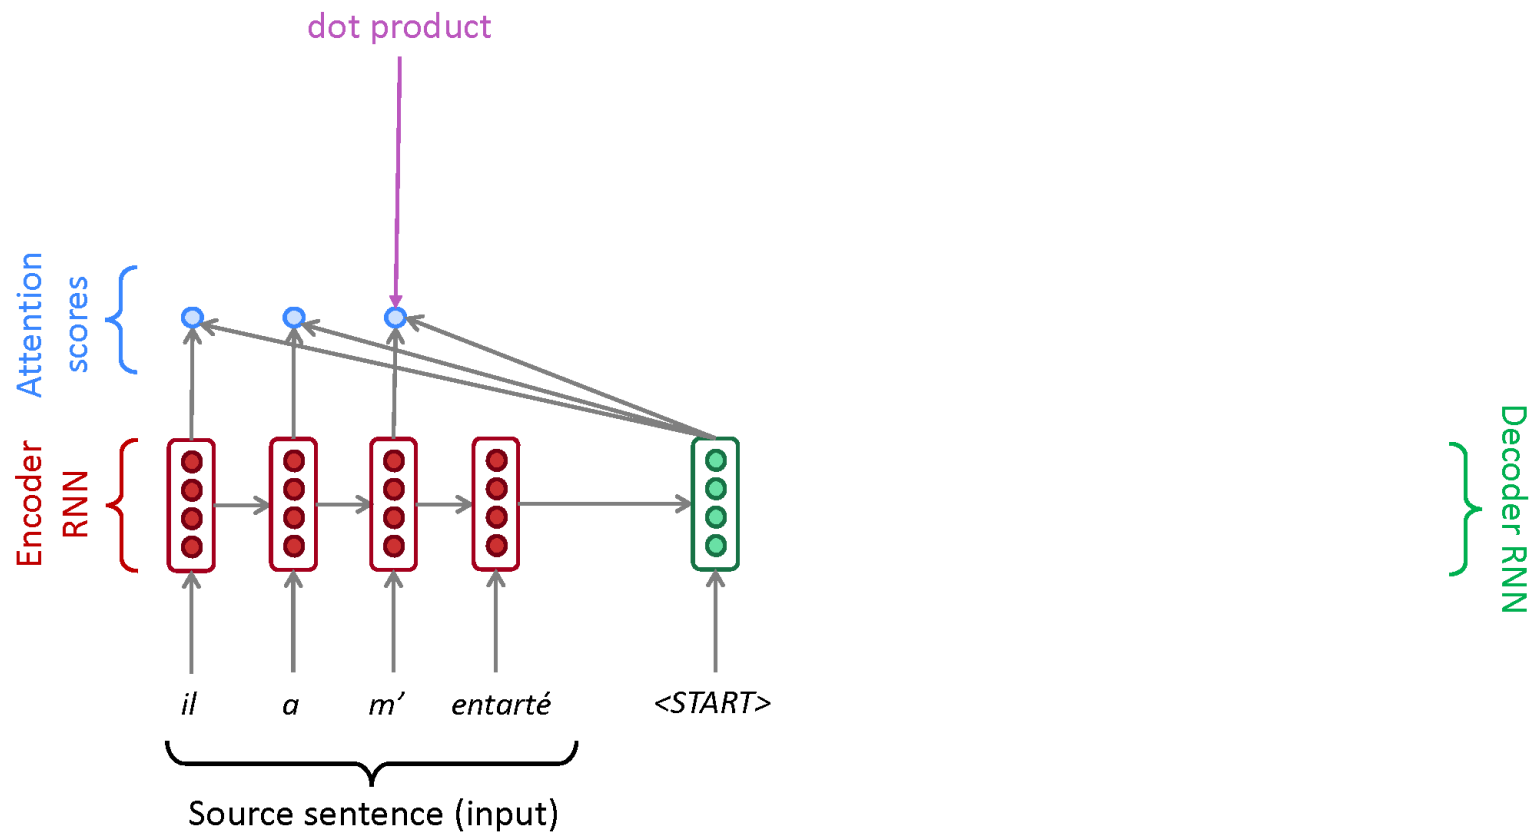

## Sequence-to-sequence with attention

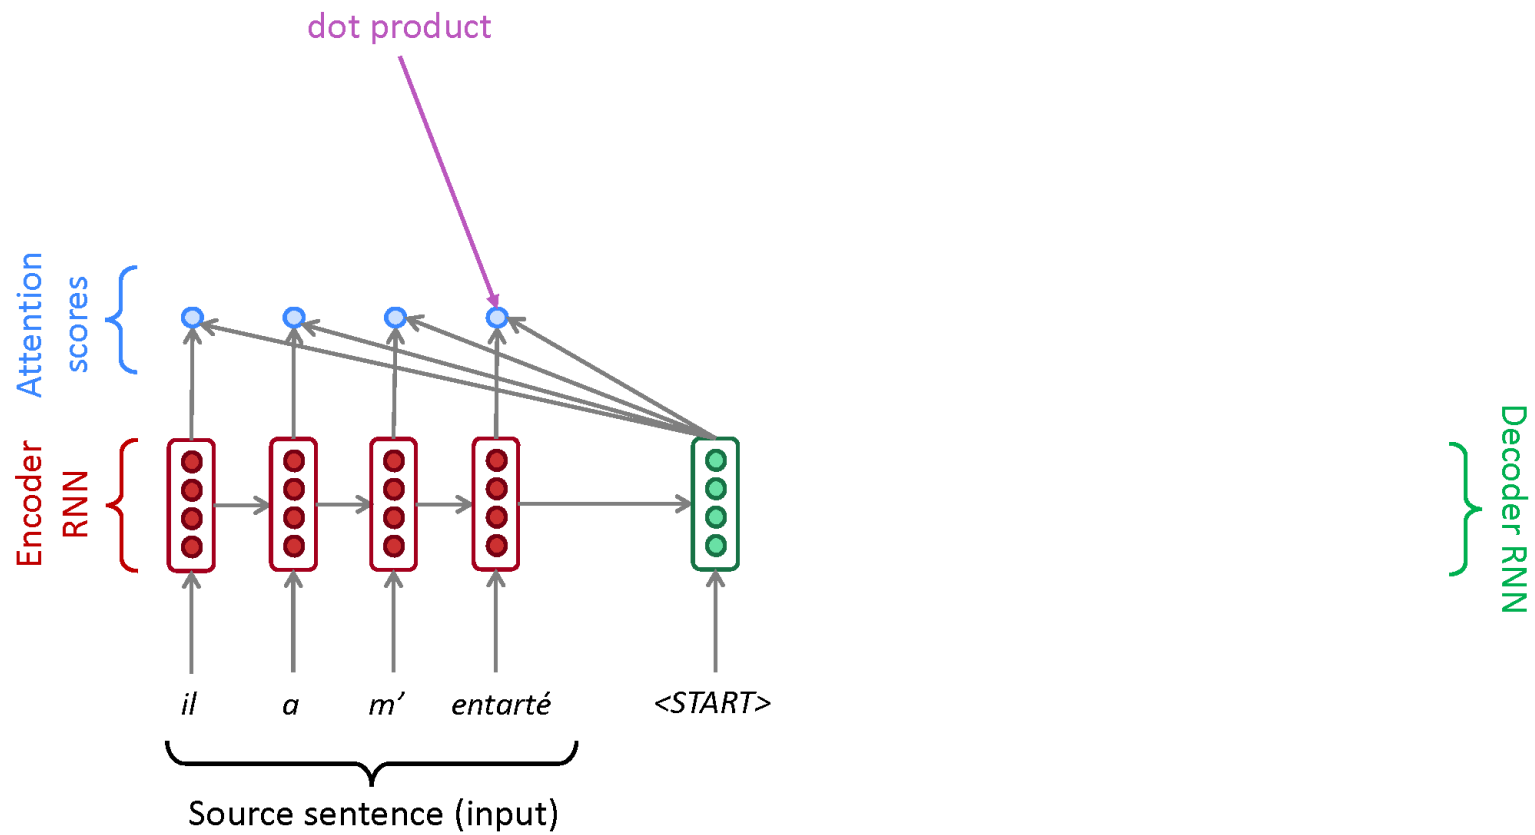

## Sequence-to-sequence with attention

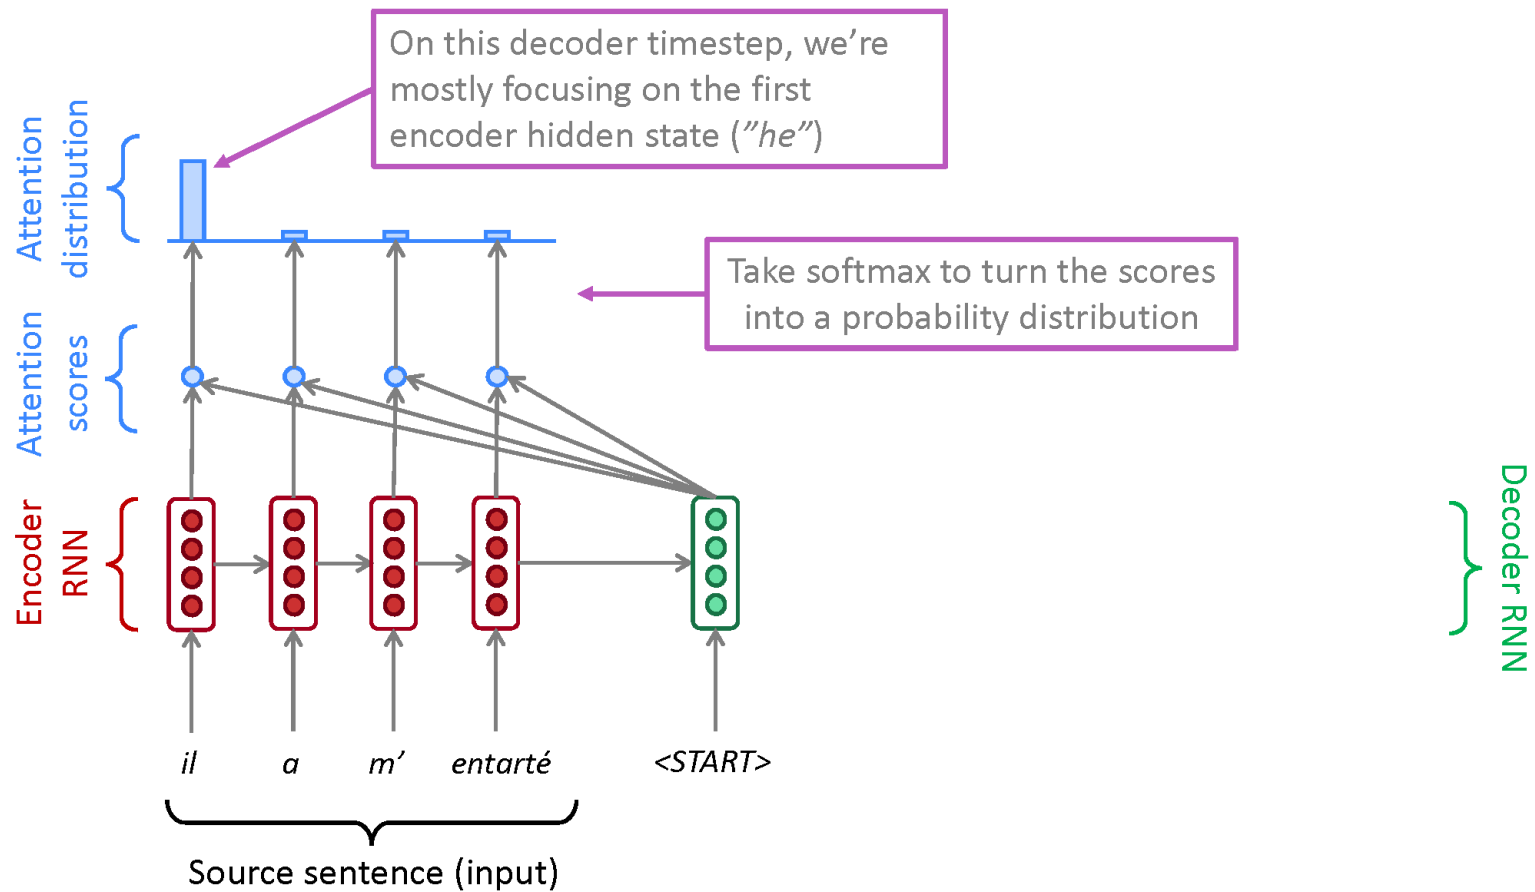

# Sequence-to-sequence with attention

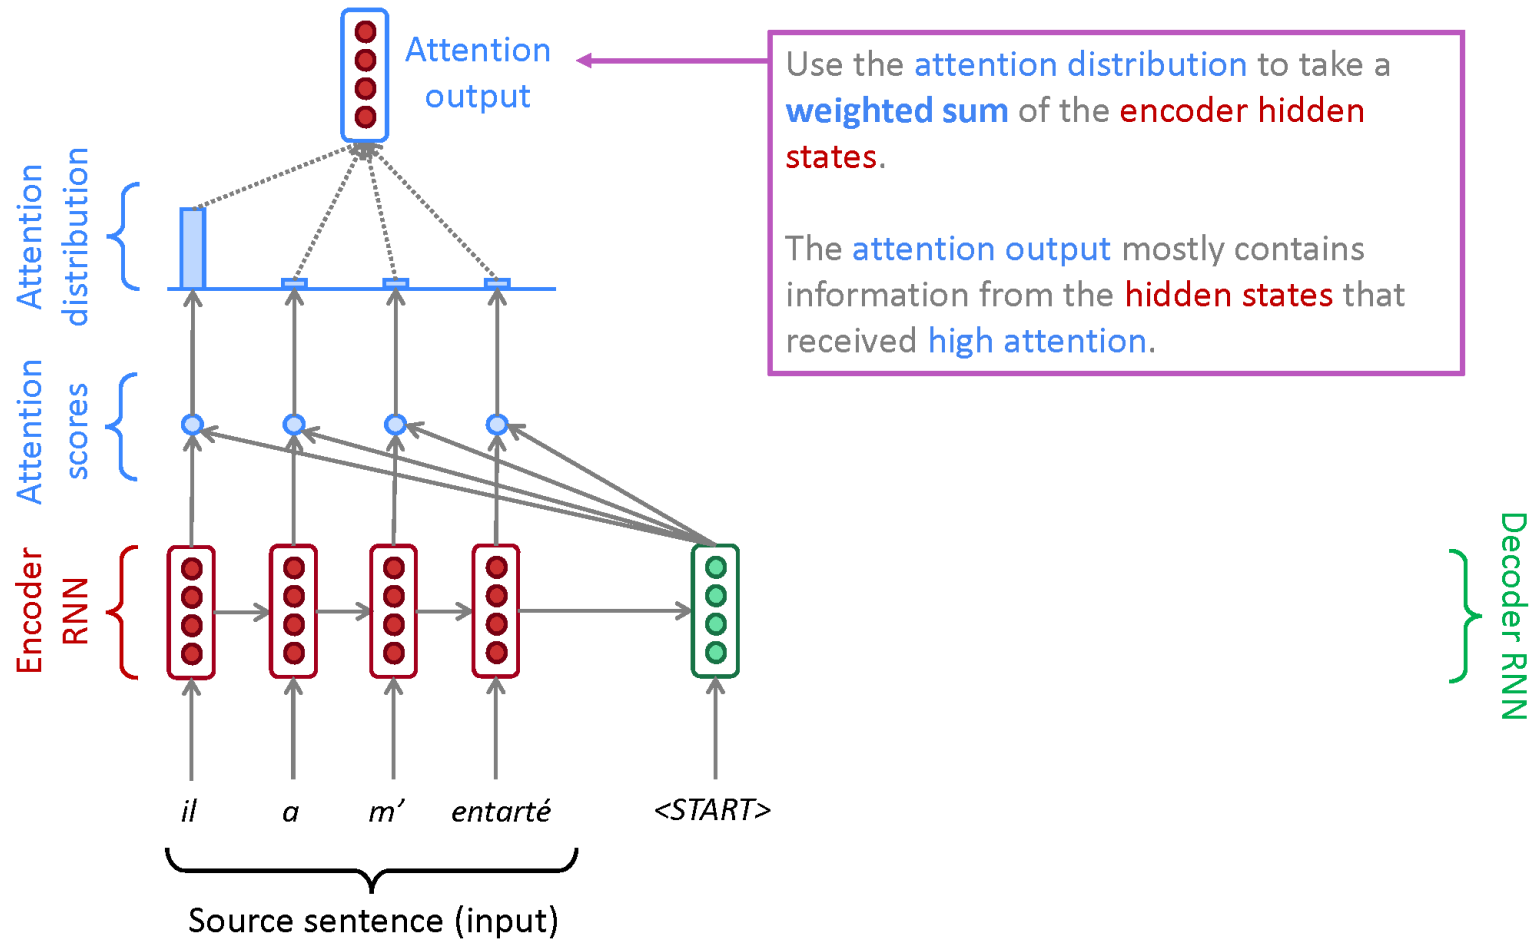

# Sequence-to-sequence with attention

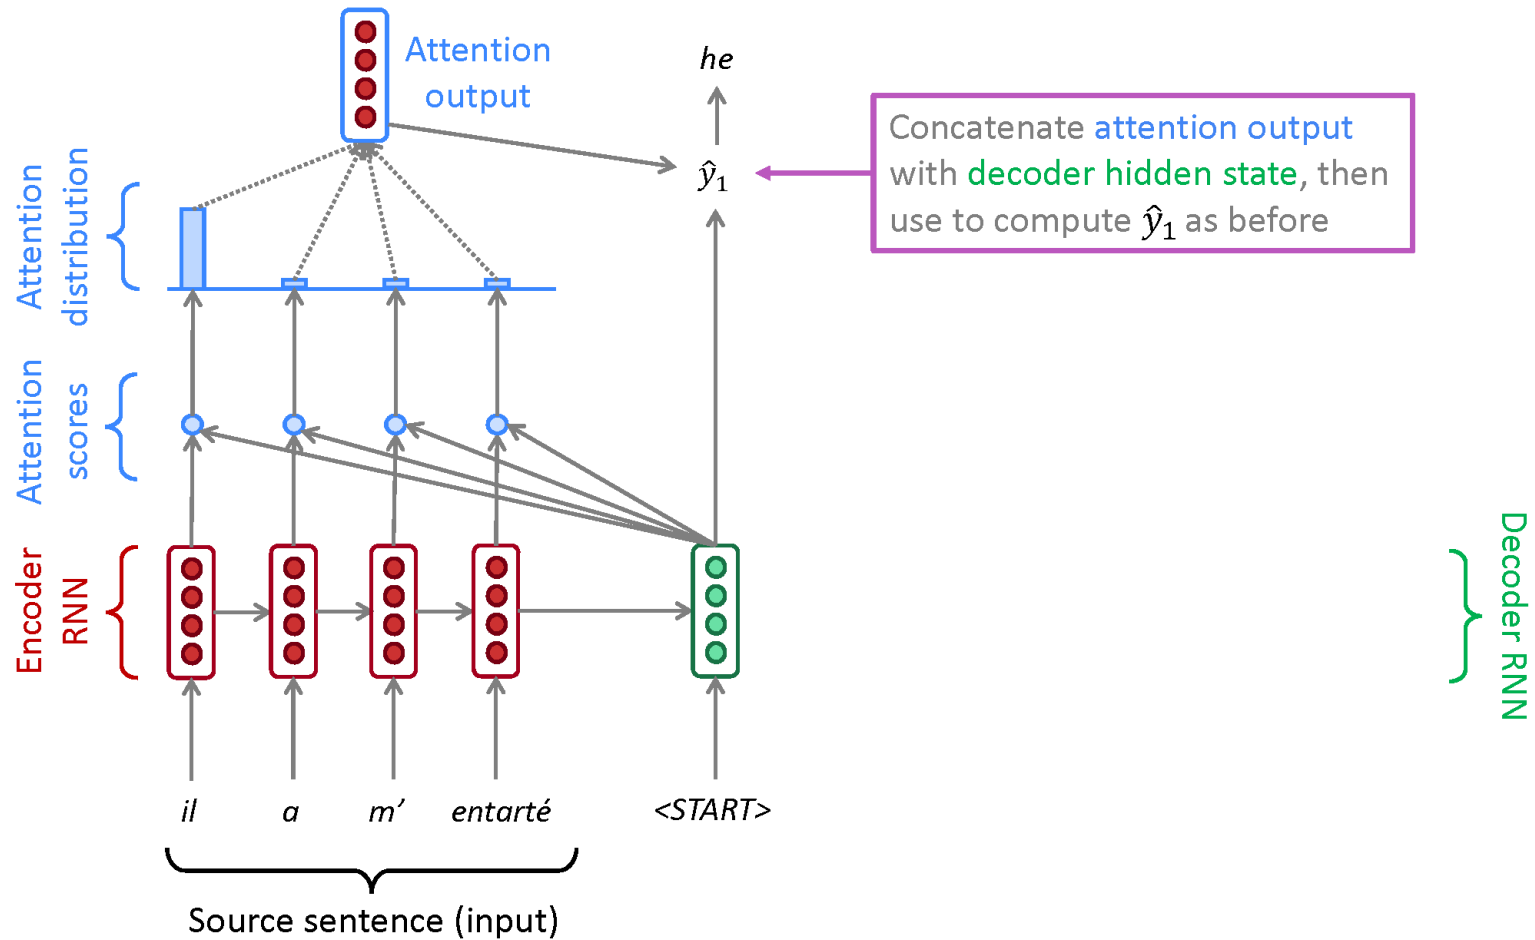

# Sequence-to-sequence with attention

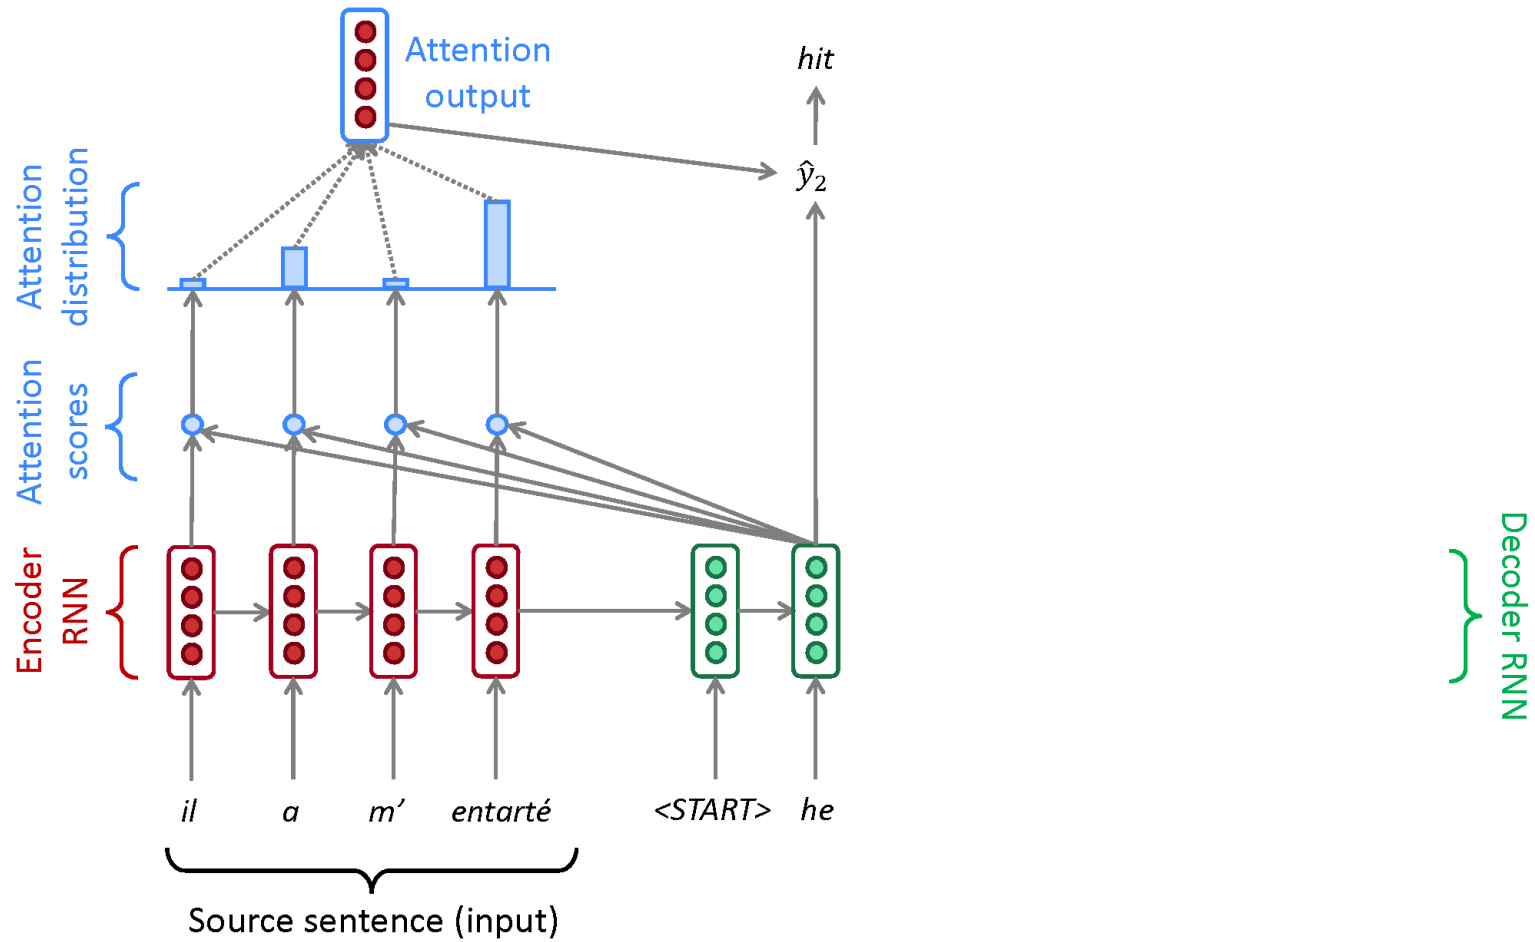

# Sequence-to-sequence with attention

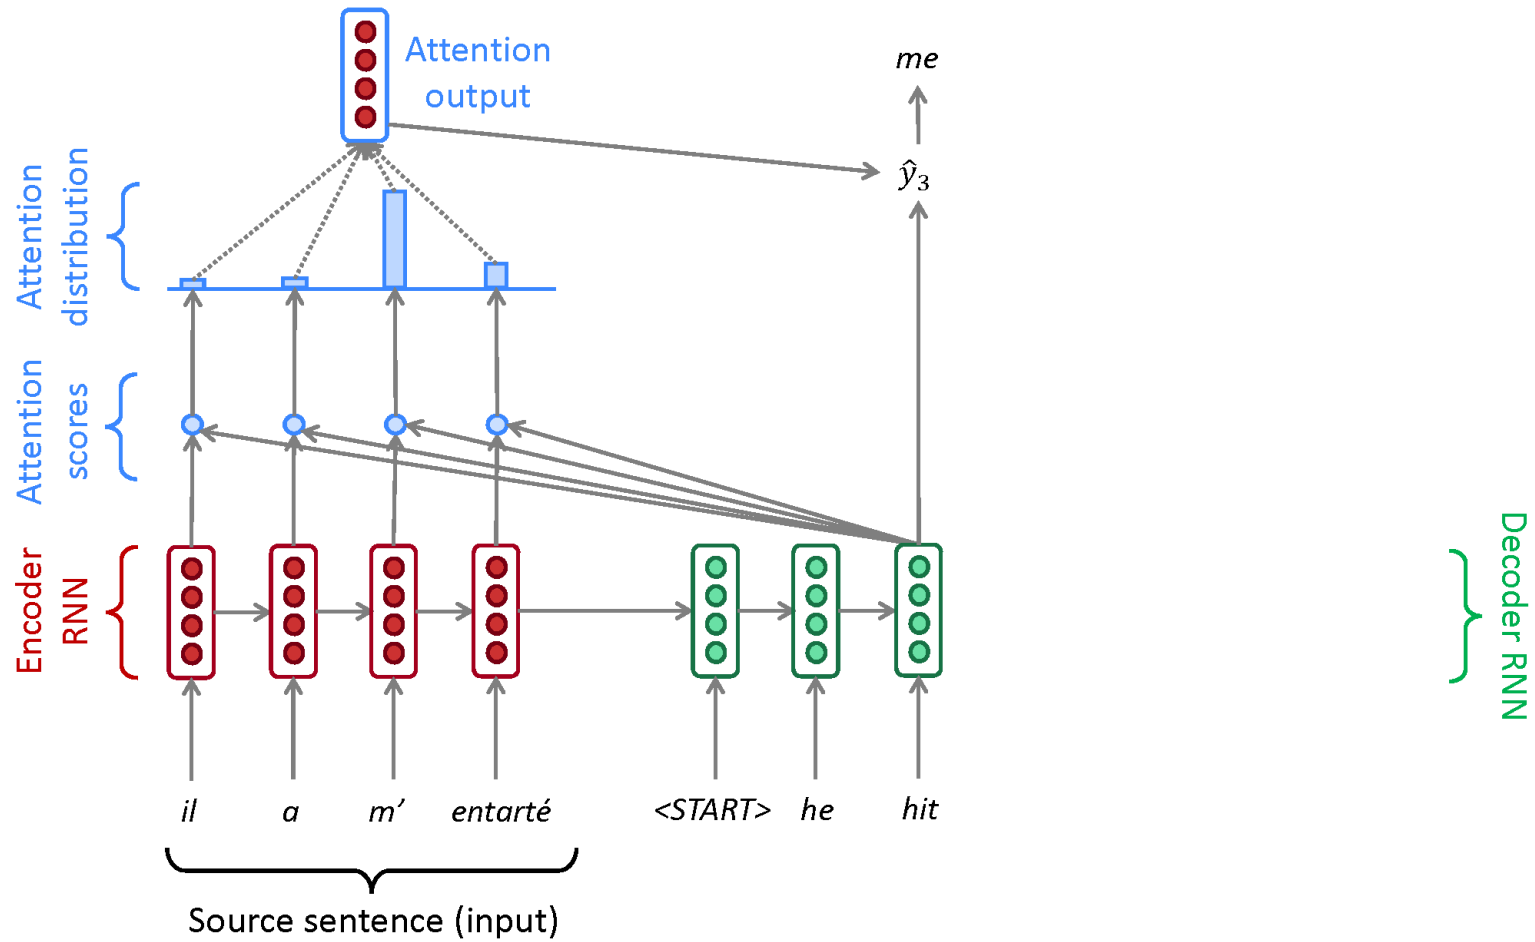

## Sequence-to-sequence with attention

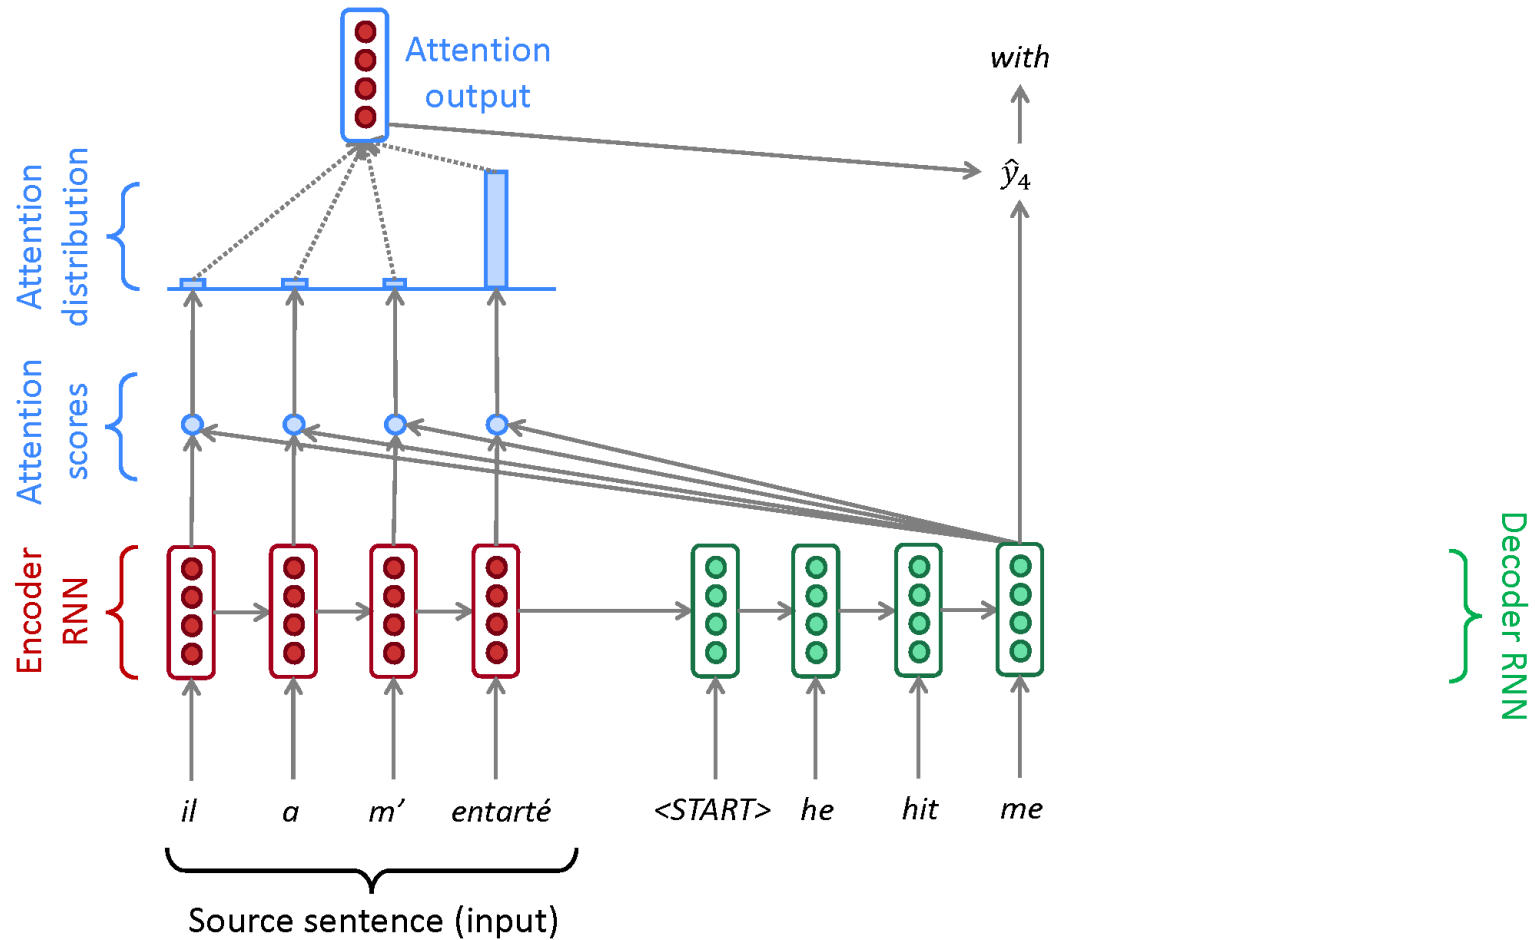

## Sequence-to-sequence with attention

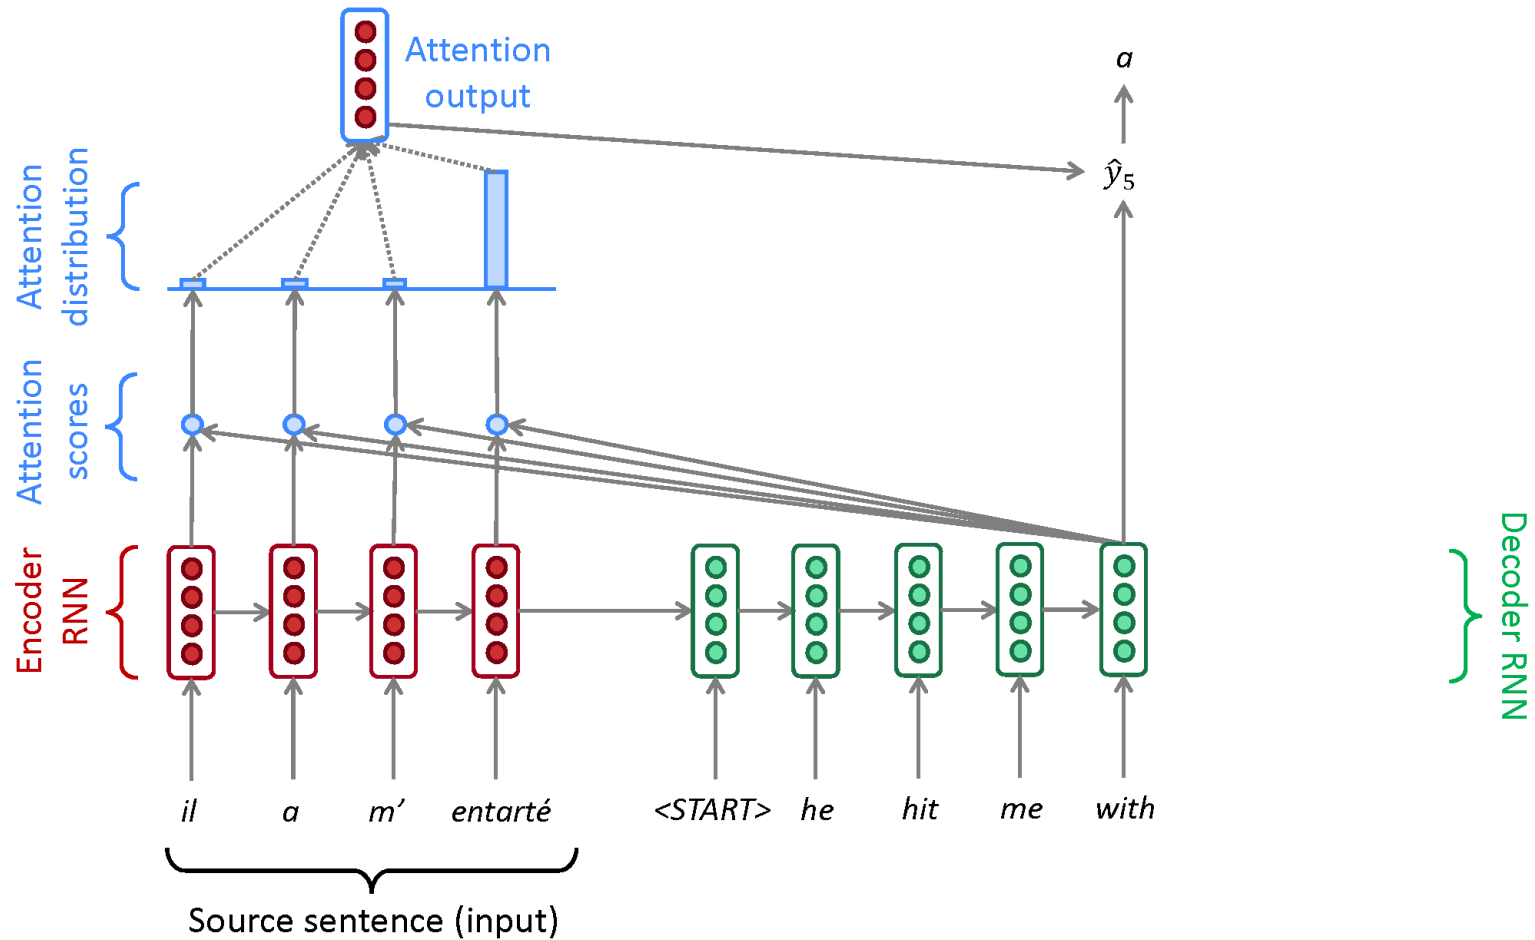

## Sequence-to-sequence with attention

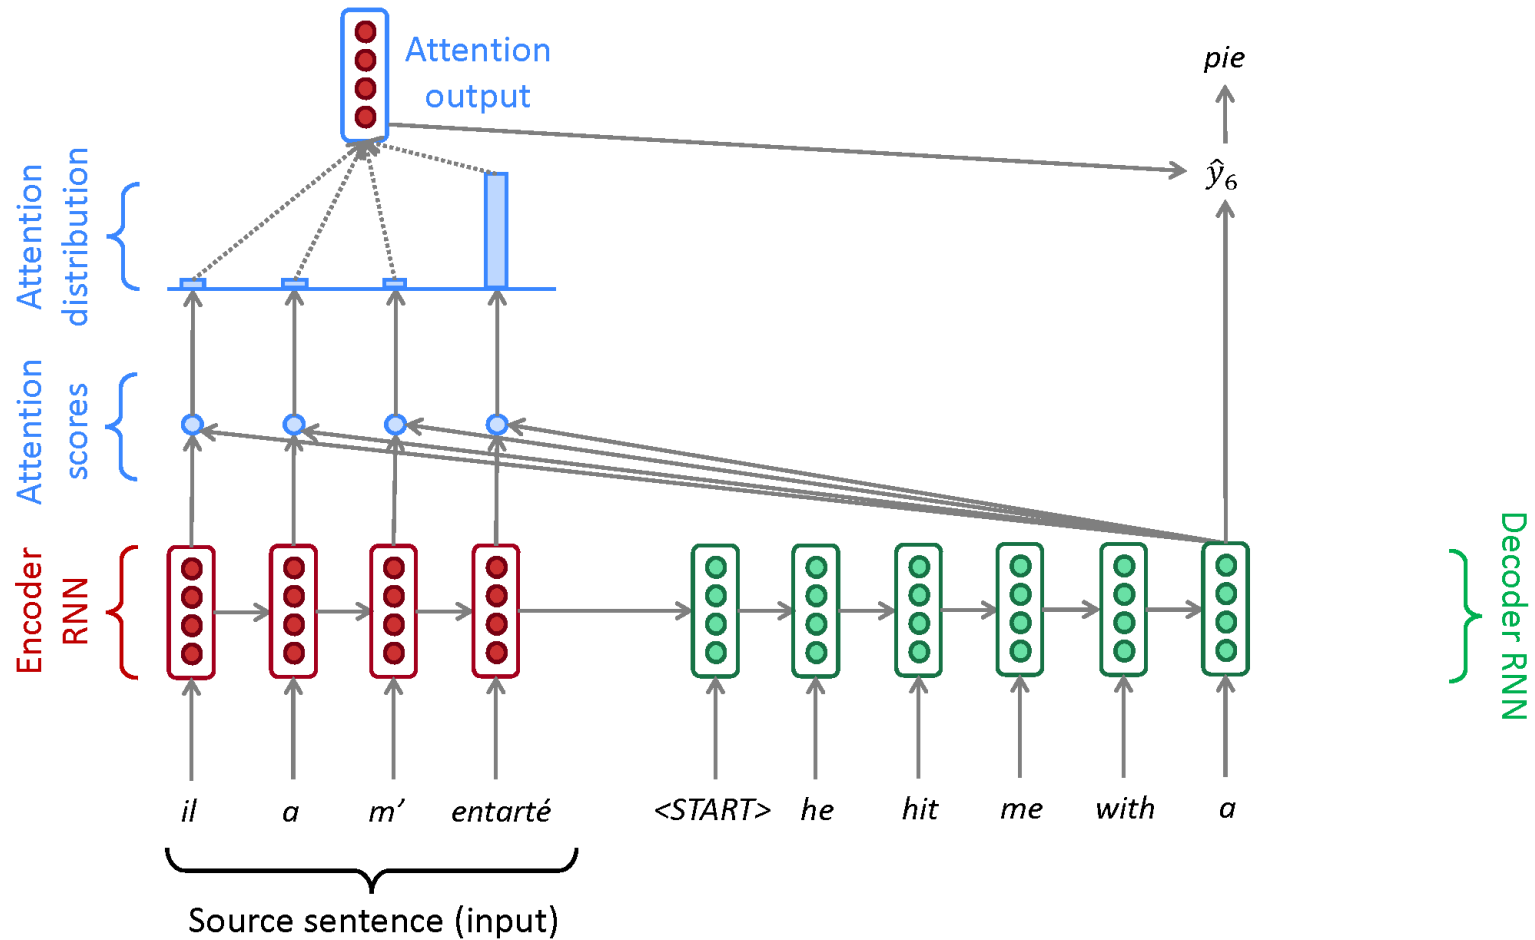

## Sequence-to-sequence with attention

## Sequence-to-sequence with attention

## Sequence-to-sequence with attention

## Attention: in equations

- We have encoder hidden states  $h_1, \dots, h_N \in \mathbb{R}^h$
- On timestep  $t$ , we have decoder hidden state  $s_t \in \mathbb{R}^h$
- We get the attention scores  $e^t$  for this step:

$$e^t = [s_t^T h_1, \dots, s_t^T h_N] \in \mathbb{R}^N$$

- We take softmax to get the attention distribution  $\alpha^t$  for this step (this is a probability distribution and sums to 1)

$$\alpha^t = \text{softmax}(e^t) \in \mathbb{R}^N$$

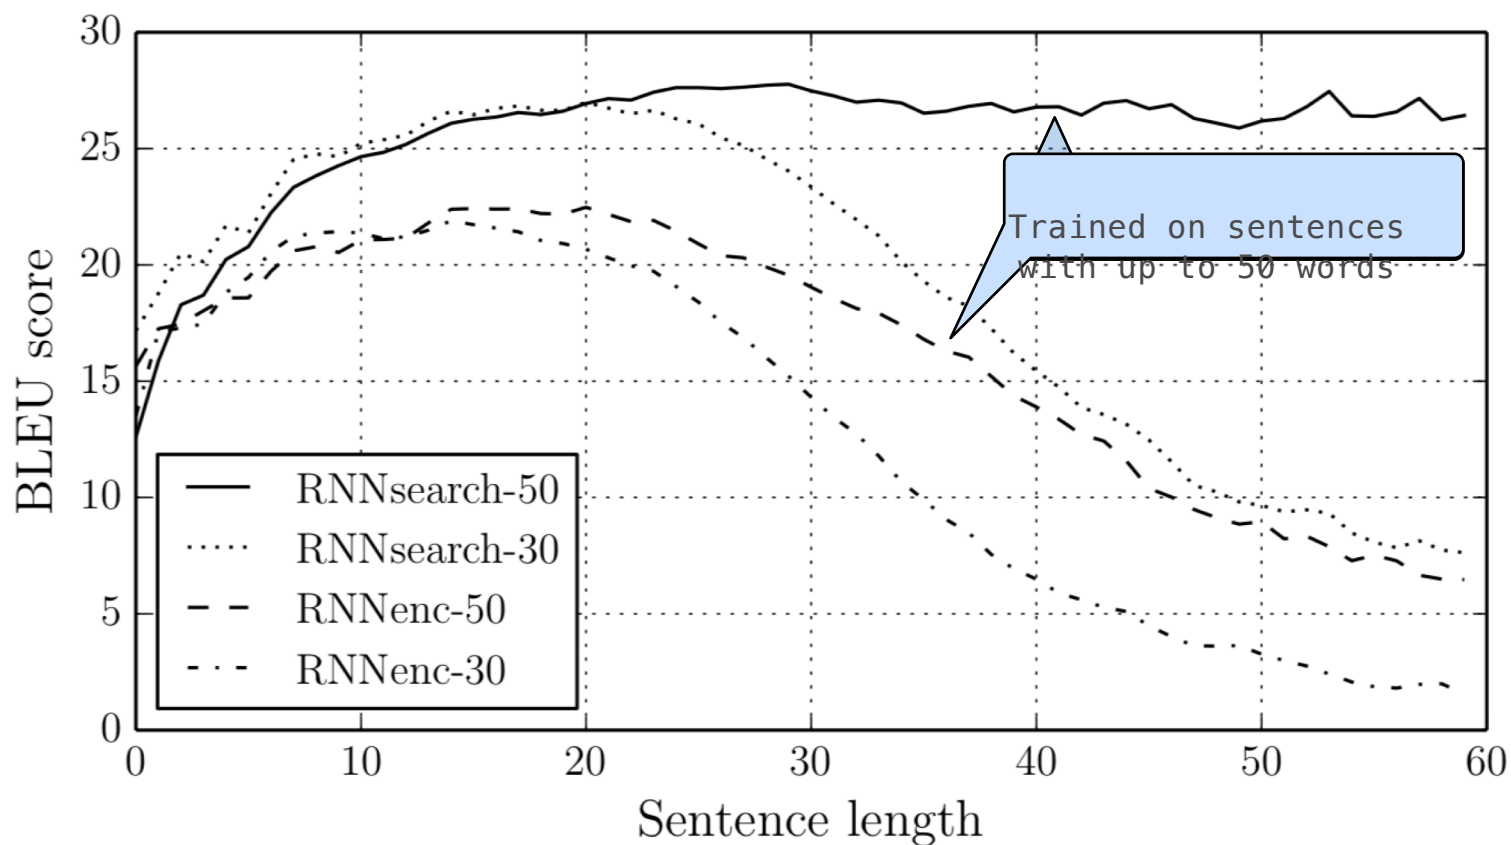

- We use  $\alpha^t$  to take a weighted sum of the encoder hidden states to get the attention output  $a_t$

$$a_t = \sum_{i=1}^N \alpha_i^t h_i \in \mathbb{R}^h$$

- Finally we concatenate the attention output  $a_t$  with the decoder hidden state  $s_t$  and proceed as in the non-attention seq2seq model

$$[a_t; s_t] \in \mathbb{R}^{2h}$$

## Impact of Attention on Long Sequence Generation

(Bahdanau et al., 2015) Neural Machine Translation by Jointly Learning to Align and Translate

## Attention is great

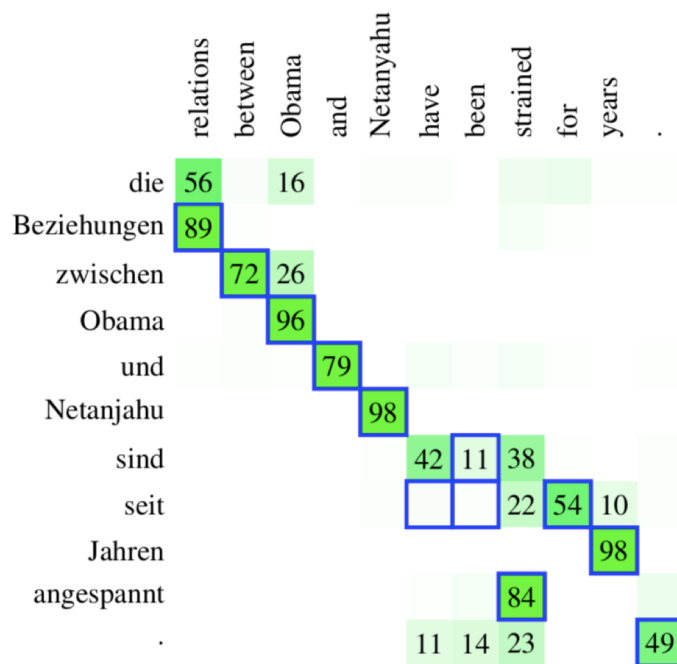

- Attention significantly **improves NMT performance**
  - It's very useful to allow decoder to focus on certain parts of the source
- Attention **solves the bottleneck problem**
  - Attention allows decoder to look directly at source; bypass bottleneck
- Attention **helps with vanishing gradient problem**
  - Provides shortcut to faraway states
- Attention provides **some interpretability**
  - By inspecting attention distribution, we can see what the decoder was focusing on
  - We get (soft) **alignment for free!**
  - This is cool because we never explicitly trained an alignment system
  - The network just learned alignment by itself

	he	hit	me	with	a	pie

## Attention vs Alignment

---

Attention activations above 0.1

English-German

German-English

## Attention is a *general* Deep Learning technique

- We've seen that attention is a great way to improve the sequence-to-sequence model for Machine Translation.
  - However: You can use attention in *many architectures* (not just seq2seq) and *many tasks* (not just MT)
- More general definition of attention:
    - Given a set of vector *values*, and a vector *query*, attention is a technique to compute a weighted sum of the values, dependent on the query.
- We sometimes say that the *query attends to the values*.
  - For example, in the seq2seq + attention model, each decoder hidden state (query) *attends to* all the encoder hidden states (values).

# Attention is a *general* Deep Learning technique

## More general definition of attention:

Given a set of vector *values*, and a vector *query*, attention is a technique to compute a weighted sum of the values, dependent on the query.

## Intuition:

- The weighted sum is a *selective summary* of the information contained in the values, where the query determines which values to focus on.
- Attention is a way to obtain a *fixed-size representation of an arbitrary set of representations* (the values), dependent on some other representation (the query).

## There are *several* attention variants

- We have some *values*  $\mathbf{h}_1, \dots, \mathbf{h}_N \in \mathbb{R}^{d_1}$  and a *query*  $\mathbf{s} \in \mathbb{R}^{d_2}$
- Attention always involves:

1. Computing the *attention scores*  $\mathbf{e} \in \mathbb{R}^N$
2. Taking softmax to get *attention distribution*  $\alpha$ :

There are  
multiple ways  
to do this

$$\alpha = \text{softmax}(\mathbf{e}) \in \mathbb{R}^N$$

3. Using attention distribution to take weighted sum of values:

$$\mathbf{a} = \sum_{i=1}^N \alpha_i \mathbf{h}_i \in \mathbb{R}^{d_1}$$

thus obtaining the *attention output*  $\mathbf{a}$  (sometimes called the *context vector*)

## Attention variants

You'll think about the relative advantages/disadvantages of these in Assignment 4!

There are **several ways** you can compute  $e \in \mathbb{R}^N$  from  $\mathbf{h}_1, \dots, \mathbf{h}_N \in \mathbb{R}^{d_1}$  and  $\mathbf{s} \in \mathbb{R}^{d_2}$ :

- Basic dot-product attention:  $e_i = \mathbf{s}^T \mathbf{h}_i \in \mathbb{R}$ 
  - Note: this assumes  $d_1 = d_2$
  - This is the version we saw earlier
- Multiplicative attention:  $e_i = \mathbf{s}^T \mathbf{W} \mathbf{h}_i \in \mathbb{R}$ 
  - Where  $\mathbf{W} \in \mathbb{R}^{d_2 \times d_1}$  is a weight matrix
- Additive attention:  $e_i = \mathbf{v}^T \tanh(\mathbf{W}_1 \mathbf{h}_i + \mathbf{W}_2 \mathbf{s}) \in \mathbb{R}$ 
  - Where  $\mathbf{W}_1 \in \mathbb{R}^{d_3 \times d_1}$ ,  $\mathbf{W}_2 \in \mathbb{R}^{d_3 \times d_2}$  are weight matrices and  $\mathbf{v} \in \mathbb{R}^{d_3}$  is a weight vector.
  - $d_3$  (the attention dimensionality) is a hyperparameter

# Transformers

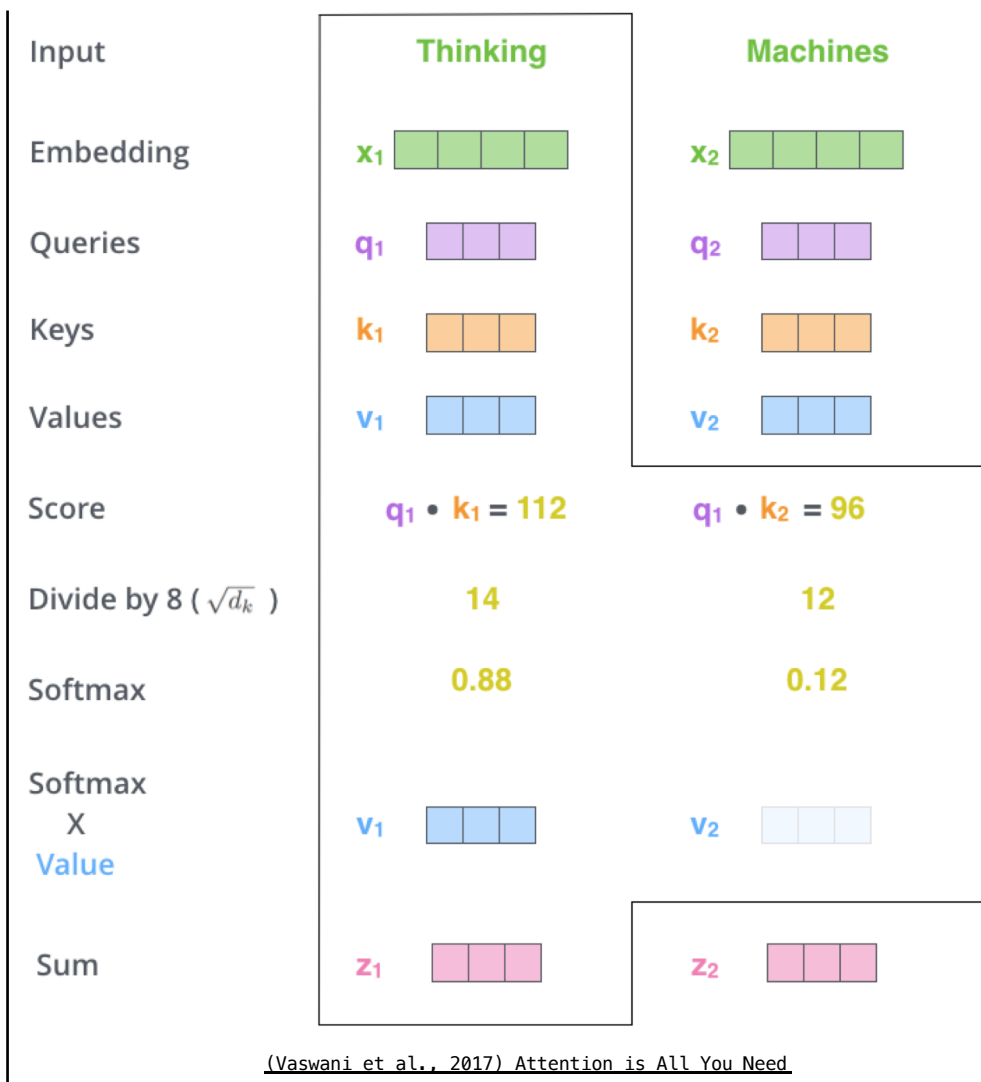

## Transformer

In lieu of an RNN,  
use ONLY attention!

High throughput &  
expressivity:  
compute queries,  
keys and values as  
(different) linear  
transformations of  
the input.

Attention weights  
are queries • keys;  
outputs are sums of  
weighted values.

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

(Vaswani et al., 2017) Attention is All You Need

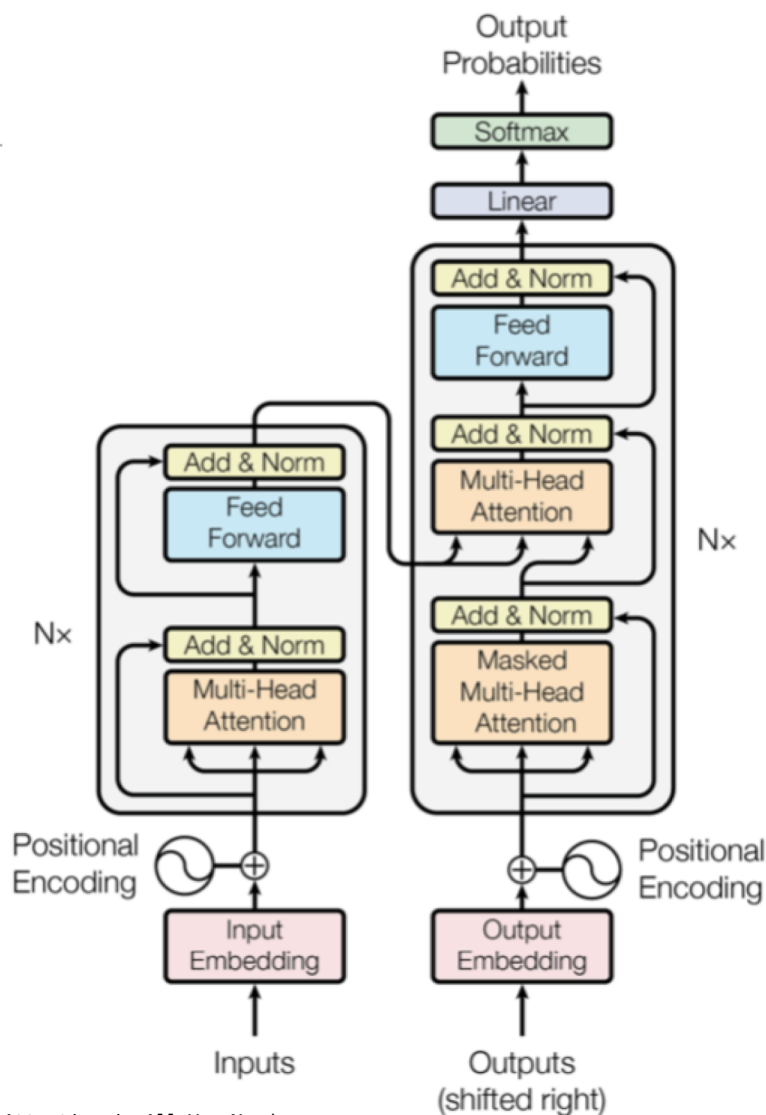

Figure: <http://jalammar.github.io/illustrated-transformer/>

## Transformer Architecture

- Layer normalization ("Add & Norm" cells) helps with RNN+attention architectures as well.
- Positional encodings can be learned or based on a formula that makes it easy to represent distance.

	EN-DE
ByteNet [18]	23.75

(Vaswani et al., 2017) Attention is All You Need

## Some Transformer Concerns

---

**Problem:** Bag-of-words representation of the input.

**Remedy:** Position embeddings are added to the word embeddings.

**Problem:** During generation, can't attend to future words.

**Remedy:** Masked training that zeroes attention to future words.

**Problem:** Deep networks needed to integrated lots of context.

**Remedies:** Residual connections and multi-head attention.

**Problem:** Optimization is hard.

**Remedies:** Large mini-batch sizes and layer normalization.

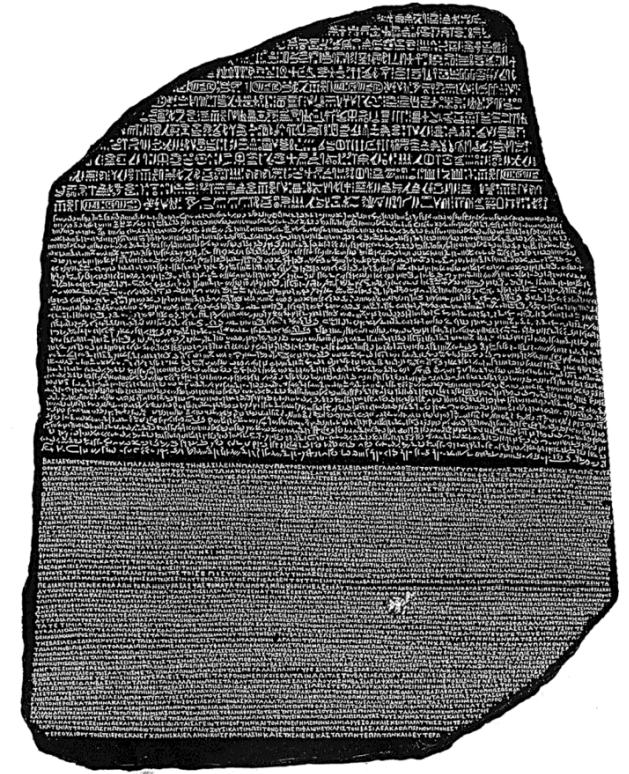

Training Data

## Bitexts

---

Where do bitexts come from?

- Careful, low level / literal translations: organizational translation processes (eg parliamentary proceedings), multilingual newsfeeds, etc
- Discovered translations (ad hoc translations on webpages, etc)
- Loose translations (multilingual Wikipedia, etc)
- Synthetic data (distillation, backtranslation, etc)

## Back Translations

---

Synthesize an en-de parallel corpus by using a de-en system to translate monolingual de sentences.

- Better generating systems don't seem to matter much.
- Can help even if the de sentences are already in an existing en-de parallel corpus!

system	EN→DE		DE→EN	
	dev	test	dev	test

Table 2: English↔German translation results (BLEU) on dev (newstest2015) and test (newstest2016). Submitted system in bold.

## Subwords

---

The sequence of symbols that are embedded should be common enough that an embedding can be estimated robustly for each, and all symbols have been observed during training.

**Solution 1:** Symbols are words with rare words replaced by UNK.

- Replacing UNK in the output is a new problem (like alignment).
- UNK in the input loses all information that might have been relevant from the rare input word (e.g., tense, length, POS).

**Solution 2:** Symbols are subwords.

- Byte-Pair Encoding is the most common approach.
- Other techniques that find common subwords aren't reliably better (but are somewhat more complicated).
- Training on many sampled subword decompositions improves out-of-domain translations.

```

vocab = {'l o w </w>' : 5, 'l o w e r </w>' : 2,
         'n e w e s t </w>':6, 'w i d e s t </w>':3}

def get_stats(vocab):
    pairs = collections.defaultdict(int)
    for word, freq in vocab.items():
        symbols = word.split()
        for i in range(len(symbols)-1):
            pairs[symbols[i],symbols[i+1]] += freq
    return pairs

def merge_vocab(pair, v_in):
    v_out = {}
    bigram = re.escape(' '.join(pair))
    p = re.compile(r'(?<!\S)' + bigram + r'(?!\S)')
    for word in v_in:
        w_out = p.sub(' '.join(pair), word)
        v_out[w_out] = v_in[word]
    return v_out

```

```

for i in range(num_merges):
    pairs = get_stats(vocab)
    best = max(pairs, key=pairs.get)
    vocab = merge_vocab(best, vocab)

```

## BPE Example

## Advantages of NMT

Compared to SMT, NMT has many advantages:

- Better performance
  - More fluent
  - Better use of context
  - Better use of phrase similarities
- A single neural network to be optimized end-to-end
  - No subcomponents to be individually optimized
- Requires much less human engineering effort
  - No feature engineering
  - Same method for all language pairs

## Disadvantages of NMT?

Compared to SMT:

- NMT is **less interpretable**
  - Hard to debug
- NMT is **difficult to control**
  - For example, can't easily specify rules or guidelines for translation
  - Safety concerns!

## NMT: the biggest success story of NLP Deep Learning

Neural Machine Translation went from a **fringe research activity** in **2014** to the **leading standard method** in **2016**

- **2014**: First seq2seq paper published
- **2016**: Google Translate switches from SMT to NMT
- **This is amazing!**
  - **SMT** systems, built by **hundreds** of engineers over many **years**, outperformed by NMT systems trained by a **handful** of engineers in a few **months**

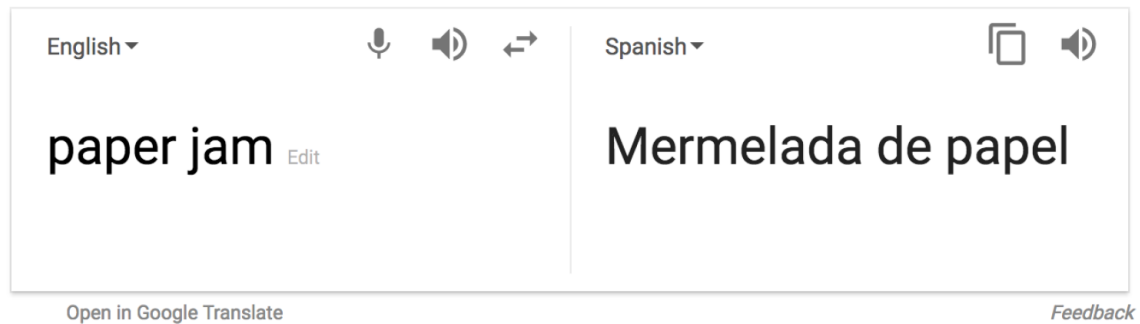

## So is Machine Translation solved?

- **Nope!**
- Many difficulties remain:
  - Out-of-vocabulary words
  - Domain mismatch between train and test data
  - Maintaining context over longer text
  - Low-resource language pairs

**Further reading:** *"Has AI surpassed humans at translation? Not even close!"*  
[https://www.skynettoday.com/editorials/state\\_of\\_nmt](https://www.skynettoday.com/editorials/state_of_nmt)

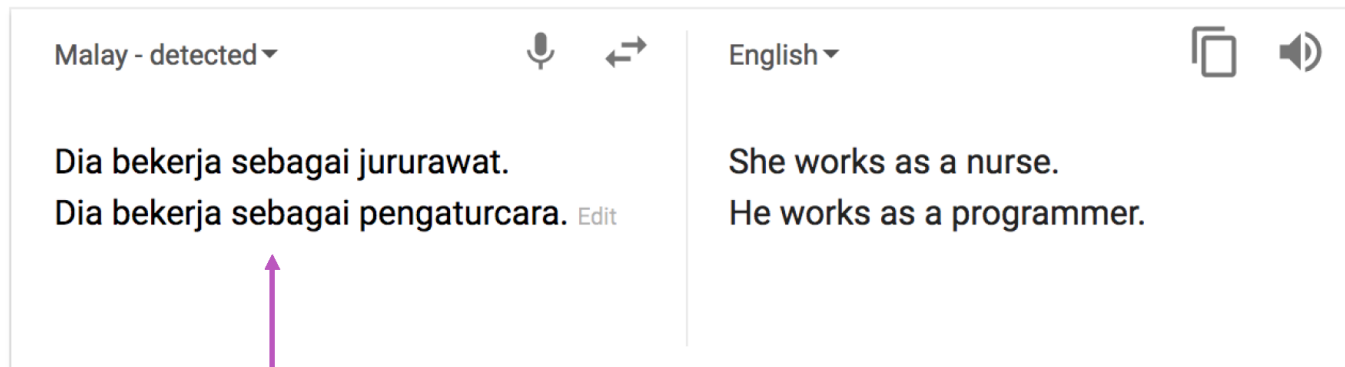

## So is Machine Translation solved?

- **Nope!**
- Using **common sense** is still hard

## So is Machine Translation solved?

- **Nope!**
- NMT picks up **biases** in training data

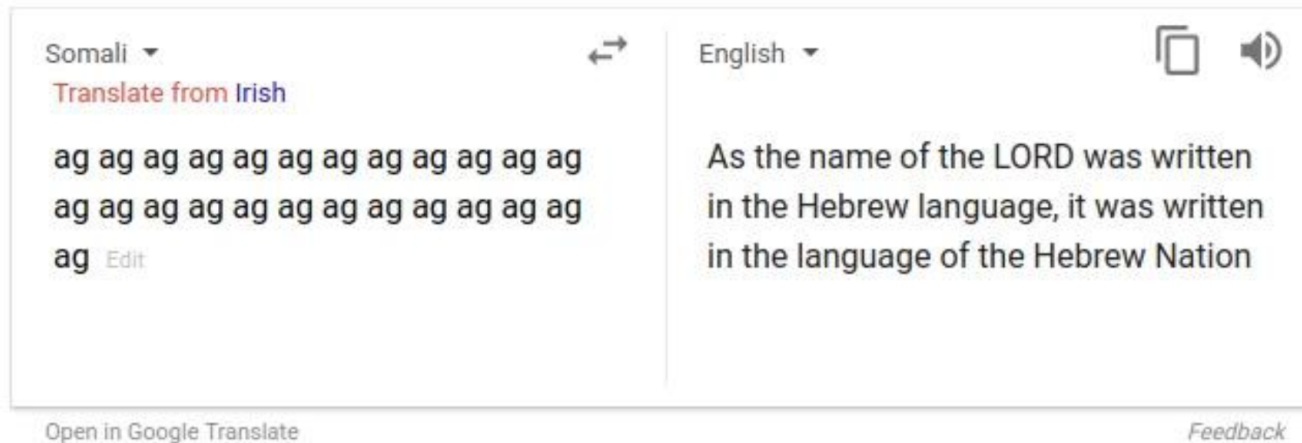

Didn't specify gender

Source: <https://hackernoon.com/bias-sexist-or-this-is-the-way-it-should-be-ce1f7c8c683c>

## So is Machine Translation solved?

- Nope!
- Uninterpretable systems do strange things

Picture source: [https://www.vice.com/en\\_uk/article/j5npeg/why-is-google-translate-spitting-out-sinister-religious-prophecies](https://www.vice.com/en_uk/article/j5npeg/why-is-google-translate-spitting-out-sinister-religious-prophecies)

Explanation: <https://www.skynettoday.com/briefs/google-nmt-prophecies>

## Summary

- We learned some history of Machine Translation (MT)
- Since 2014, **Neural MT** rapidly replaced intricate Statistical MT
- **Sequence-to-sequence** is the architecture for NMT (uses 2 RNNs)
- **Attention** is a way to *focus on particular parts* of the input
  - Improves sequence-to-sequence a lot!
